Series Acknowledgements

Jonathan Kingdon, David Happold, Thomas Butynski,

Michael Hoffmann, Meredith Happold and Jan Kalina

The editors wish to record their thanks to all the authors who have contributed to *Mammals of Africa* for their expert work and for their patience over the very protracted period that these volumes have taken to materialize. We also thank the numerous reviewers who have read and commented on earlier drafts of this work.

We are also grateful for the generosity of our sponsoring patrons, whose names are recorded on our title pages, who have made the publication of these volumes possible.

Special thanks are due to Andy Richford, the Publishing Editor at Academic Press, who initiated and supported our work on *Mammals of Africa*, from its inception up to the point where Bloomsbury Publishing assumed responsibility, and to Nigel Redman (Head of Natural History at Bloomsbury), David and Namrita Price-Goodfellow at D & N Publishing, and the whole production team who have brought this work to fruition. We also acknowledge, with thanks, Elaine Leek who copy-edited every volume. We are grateful to Chuck Crumly, formerly of Academic Press and now the University of California Press, for being our active advocate during difficult times.

We have benefited from the knowledge and assistance of scholars and staff at numerous museums, universities and other institutions all over the world. More detailed and personal acknowledgements follow from the editors of each volume.

The editors are also grateful to the coordinating team of the Global Mammal Assessment, an initiative of the International Union for Conservation of Nature (IUCN), which organized a series of workshops to review the taxonomy and current distribution maps for many species of African mammals. These workshops were hosted by the Zoological Society of London, Disney's Animal Kingdom, the Owston's Palm Civet Conservation Programme, and the Wildlife Conservation Research Unit at the University of Oxford; additionally, IUCN conducted a review of the maps for the large mammals by the Specialist Groups of the Species Survival Commission. We owe a particular word of thanks to all the staff and personnel who made these workshops possible, and to the participants who attended and provided their time and expertise to this important initiative. We also thank IUCN for permission to use data from the *IUCN Red List of Threatened Species*.

Acknowledgements for Volume IV

Meredith Happold and D. C. D. Happold

We owe a great debt of gratitude to the many people who have helped and encouraged us with our research on African small mammals for nearly 50 years and hence have contributed enormously to this volume. When we were beginning our research, the following colleagues were marvellous sources of inspiration: Frank Ansell†, Fritz Dieterlen, John Edwards Hill†, Dieter Kock, Karl Koopman†, Erwin Kulzer, Waldo Meester†, Francis Petter†, Don Rosevear†, Hank Setzer† and Reay Smithers†. We also acknowledge the many collectors who, from the nineteenth century onwards, collected specimens, often in remote parts of Africa and often under appallingly difficult conditions, and sent them back to museums in Britain, Europe and North America where they still provide invaluable information. We are also extremely grateful to our colleagues (many of whom are authors of profiles in this volume) who have given so very generously of their time and knowledge to make this volume possible. [† Deceased]

This volume owes a great deal to the museums that house specimens of African small mammals. For many years, we have visited museums whenever the opportunity has occurred, and we are most grateful to the curators and their assistants who have helped during our visits: David Harrison, Paul Bates and Malcolm Pearch (Harrison Zoological Institute, Sevenoaks, England), Gabor Csorba (Hungarian Natural History Museum), Francis Petter† and Jacques Cuisin (Museum National d'Histoire Naturelle, Paris, France), Lydia Kigo (National Museum of Kenya, Nairobi, Kenya), Frederike Spitzenberger and Barbara Herzig (Naturhistorisches Museum, Vienna, Austria), Wim Wendelen (Royal Museum of Central Africa, Tervuren, Belgium), Judith Eger (Royal Ontario Museum, Toronto, Canada), Dieter Kock (Senckenberg Museum, Frankfurt, Germany), Fritz Dieterlen (Staatliches Museum für Naturkunde, Stuttgart, Germany), Teresa Kearney and Christian Chimimba (Transvaal Museum, Pretoria, South Africa) and Rainer Hutterer (Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany). We owe a special debt of gratitude to the Natural History Museum, London, England (formerly British Museum of Natural History), especially Gordon Corbet, John Edwards Hill†, Robert Hayman†, Paula Jenkins, Jean Ingles, Daphne Hills and Louise Tomsett who have allowed us (since 1964) to examine the collections and have assisted us in numerous ways. Particular thanks also are due to Michael and Mona Ensor and Sara Churchfield in London, the Ostermeyer and Schlöder families in Bonn, our friends in Corniche Verte, Brussels, and Mike and Anne-Marie Swift in Nairobi, who provided us with welcoming homes and sustenance after our busy days in museums.

We wish to thank the various universities, where one or both of us has been employed, for their support for our studies on African mammals: Australian National University, Canberra, Australia; University of Ibadan, Nigeria; University of Khartoum, Sudan; and University of Malawi, Zomba, Malawi. The Australian Research Grants Committee also provided funds for our more recent work in Malawi.

This volume would not have been possible without the contributions and invaluable collaboration from the authors themselves. Many authors had other commitments and found it extremely hard to find the time for writing profiles. Great credit is due to them for their dedication and perseverance, and for accepting that many of the sections (especially the descriptions) needed heavy editing to ensure that the profiles became uniform in terminology and content, compatible and comparable, and hence functional and unambiguous. Our thanks are also due to the many reviewers (listed here in alphabetical order) who reviewed profiles for this volume: Stéphane Aulagnier, Paul Bates, Rod Baxter, Petr Benda, Nigel Bennett, Wim Bergmans, Gary Bronner, Charles Calisher, Gabor Csorba, J. F. Dahl, Jan Decher, Nico Dippenaar, Njikoha Ebigbo, Judith Eger, Jakob Fahr, Roger Fons, Jiří Gaisler, Norberto Giannini, Werner Haberl, Rainer Hutterer, David Jacobs, Jenny Jarvis, Teresa Kearney, Julian Kerbis Peterhans, Kazimierz Kowalski, Barbara Rzebik-Kowalska, Dieter Kock, Erwin Kulzer, Emile Lecompte, Anthony Maddock, Conrad Matthee, Françoise Poitevin, Nigel Reeve, Manuel Ruedi, Duane Schlitter, Nancy Simmons, Katja Soer, Sandy Sowler, Peter Taylor, Michel Thévenot, Erik Thorn, Don Thomas, Yves Tupinier, Victor Van Cakenberghe, Peter Vogel and Johan Watson.

We also acknowledge, with deep gratitude, all who have provided specialist knowledge and advice: in particular, Paul Bates, Wim Bergmans, Patrick Boland, Gary Bronner, Charles Calisher, Mike Carleton, Laurent Granjon, Colin Groves, David Harrison, Tony Hutson, Dieter Kock, Ernest Seamark, Nancy Simmons, Victor Van Cakenberghe and Marianne Volleth. We also thank Stéphane Aulagnier who provided the French names of bats, Jakob Fahr and Cornelia Rumpff who provided the German names of bats, and Anke Hoffman who provided many of the German names of other small mammals.

We are extremely grateful to the coordinating team of the Global Mammal Assessment, an initiative of the International Union for the Conservation of Nature (IUCN) and The Zoological Society of London who organized the workshops referred to in the Series Acknowledgements. We are also especially grateful to Zoe Cokeliss who digitized all the distribution maps of the small mammals.

Mammals of Africa: *An Introduction and Guide*

David Happold, Michael Hoffmann, Thomas Butynski and Jonathan Kingdon

Mammals of Africa is a series of six volumes that describes, in detail, every extant species of African land mammal that was recognized at the time the profiles were written (Table 1). This is the first time that such an extensive coverage has been attempted; all previous books and field guides have either been regional in coverage, or have described a selection of mammal species – usually the larger species. These volumes demonstrate the diversity of Africa's mammals, summarize what is known about the distribution, ecology, behaviour and conservation status of each species, and serve as a guide to identification.

Africa has changed greatly in recent decades because of increases in human populations, exploitation of natural resources, agricultural development and urban expansion. Throughout the continent, extensive areas of forest have been destroyed and much of the forest that remains is degraded and fragmented. Savanna habitats have been altered by felling of trees and development for agriculture. Many of the drier areas are threatened with desertification. As a result, the abundance and geographic ranges of many species of mammals have declined – some marginally, some catastrophically, some to

extinction. Hence, it seems appropriate that our knowledge of each species is recorded now, on a pan-African basis, because the next few decades will see even more human-induced changes. How such changes will affect each mammalian species is uncertain, but this series of volumes will act as a baseline for assessing future change.

The study of African mammals has taken several stages. During the era of European exploration and colonization, the scientific study of African mammals was largely descriptive. Specimens that were sent to museums were described and named. As more specimens became available, and from different parts of the Continent, there was increasing interest in distribution and abundance, and in the ecological and behavioural attributes of species and communities. At first, it was the largest and most easily observed species that were the focus of most studies but, as new methodologies and equipment became available, the smaller, seldom seen, secretive species became better known. Many species were studied because of their suspected role in diseases of humans and livestock, and because they were proven or potential 'pests' in agricultural systems. During the past decade or so, there has been greater emphasis on the karyotypic and molecular/genetic characters of species. These studies have produced a wealth of information, especially during the past 40 years or so. These volumes are not only a distillation of the huge literature that now exists on African mammals: they also contain much previously unpublished information.

There is a huge discrepancy among species in the amount of information available. Some species have been studied extensively for many years, especially the so-called 'game species', some species of primates and a few species that are widespread and/or easily observed. In contrast, other species are known only by one or a few specimens, and almost nothing is known about them. Likewise, some areas and countries have been well studied, while other areas and countries have been neglected. During the preparation of these volumes, the editors have often been surprised by the wealth of information about some species when little was anticipated, and by the paucity of information about others, some of which were assumed to be 'well known'. In addition to presenting information that is based on sound scientific evidence, the aims of these volumes are to point out where there are gaps in knowledge and to correct inaccurate information that has become embedded in the literature. For most taxa, the detail provided in the species profiles allows accurate identification.

Mammals of Africa comprises six volumes (Table 2). The volumes consist mainly of species profiles – each profile being a detailed

Table 1. The mammals of Africa.

| Order | Number of families | Number of genera | Number of species |
|-----------------|--------------------|------------------|-------------------------|
| Hyracoidea | 1 | 3 | 5 |
| Proboscidea | 1 | 1 | 2 |
| Sirenia | 2 | 2 | 2 |
| Afrosoricida | 2 | 11 | 24 |
| Macroscelidea | 1 | 4 | 15 |
| Tubulidentata | 1 | 1 | 1 |
| Primates | 4 | 25 | 93 |
| Rodentia | 15 | 98 | 395 ^a |
| Lagomorpha | 1 | 5 | 13 |

Table 2. The six volumes of *Mammals of Africa*.

| Volume | Contents | Number of species | Editors |
|--------|--|-------------------|--|
| I | Introductory chapters. Afrotheria (Hyraxes, Elephants, Dugong, Manatee, Otter-shrews, Golden-moles, Sengis and Aardvark) | 49 | Jonathan Kingdon, David C. D. Happold, Michael Hoffmann, Thomas M. Butynski, Meredith Happold and Jan Kalina |
| II | Primates | 93 | Thomas M. Butynski, Jonathan Kingdon and Jan Kalina |
| III | Rodents, Hares and Rabbits | 408 | David C. D. Happold |
| IV | Hedgehogs, Shrews and Bats | 380 | Meredith Happold and David C. D. Happold |
| V | Carnivores, Pangolins, Equids and Rhinoceroses | 93 | Jonathan Kingdon and Michael Hoffmann |
| VI | Pigs, Hippopotamuses, Chevrotain, Giraffes, Deer and Bovids | 93 | Jonathan Kingdon and Michael Hoffmann |

account of the species. They have been edited by six editors who distributed their work according to the orders with which they were most familiar. Each editor chose authors who had extensive knowledge of the species (or higher taxon) and, preferably, had experience with the species in the field. Each volume follows the same general format with respect to arrangement, subheadings and contents. Because *Mammals of Africa* has contributions from 356 authors (each with a different background and speciality), and because each volume was edited by one or more editors (each with a different perspective), it has not been possible or even desirable to ensure exact consistency throughout. Species profiles are not intended to be exhaustive literature reviews, partly for reasons of space. None the less, they are written and edited to be as comprehensive as possible, and to lead the reader to the most important literature for each species. Inevitably, not all information available could be accommodated for the better-known species, and so such profiles are a précis of available knowledge. Extensive references in the text alert the reader to more detailed information.

In addition to the species profiles, there are profiles for the higher taxa (genera, families, orders, etc.). Thus, there is a profile for each order, for each family within the order, for each genus within the family, and for each species within the genus. For some orders there are additional taxonomic levels, for example, tribes (e.g. in Bovidae), subgenera (e.g. in *Procolobus*) and species-groups, or 'super-species' (e.g. in *Cercopithecus*). The taxonomy used in these volumes mostly follows that presented in the third edition of *Mammal Species of the World: A Geographic and Taxonomic Reference* (2005), although authors have employed alternative taxonomies when there were good reasons for doing so. Volume I differs from the other volumes in that it contains a number of introductory chapters about Africa and its environment, and about African mammals in general.

The continent of Africa

For the purposes of this work, 'Africa' is defined as the continent of Africa (bounded by the Mediterranean Sea, the Atlantic Ocean, the Indian Ocean, the Red Sea and the Suez Canal) and the islands on the continental shelf that, at some time in their history, have been joined to the African continent. The largest of the 'continental islands' are Zanzibar (Unguja), Mafia and Bioko (Fernando Po). All 'oceanic islands', e.g. São Tomé, Príncipe, Annobón (Pagulu), Madagascar, Comoros, Seychelles, Mauritius, Socotra, Canaries, Madeira and Cape Verde are excluded, with the exception of Pemba, which is included because of its close proximity (ca. 50 km) to the mainland.

The names of the countries of Africa are taken from the *Times Atlas* (2005). The Republic of Congo is referred to as 'Congo' and the Democratic Republic of Congo (formerly Zaire) as 'DR Congo'. Smaller geographical or administrative areas within countries are rarely referred to except for Provinces in South Africa, which are used extensively in the literature. Maps showing the political boundaries of Africa (Figure 1a), the Provinces of South Africa (Figure 1b) and the physical features of Africa with the major rivers and lakes (Figure 1c) are provided, as well as a list of the 47 countries together with their previous names that are used in the older literature on African mammals (Table 3).

Africa is the second largest continent in the world (after Asia), but it differs from other continents (except Australia and Antarctica) in being essentially an island. At various times in the past, Africa has been joined to other continents – a situation that has had a strong influence on the fauna and flora of the continent. Africa is a vast continent (29,000,000 km², 11,200,000 mi²) that straddles the Equator, with about two-thirds of its area in the northern hemisphere and one-third in the southern hemisphere. As a result, Africa has many varied climates (with seasons in each hemisphere being 6 months out of phase), many habitats (including deserts, savannas, woodlands, swamps, rivers, lakes, moist forests, monsoon forests, mountains and glaciers), and altitudes ranging from 155 m (509 ft) below sea level at L. Assal, Djibouti, in the Danakil (Afar) Depression, to 5895 m (19,341 ft) on Mt Kilimanjaro, Tanzania. Africa is comprised of 47 countries, some of which are very large (e.g. Sudan [2,506,000 km²; 967,000 mi²], Algeria (2,382,000 km², 920,000 mi²], and Democratic Republic of Congo [2,345,000 km², 905,000 mi²]), and others that are relatively small (e.g. Djibouti [23,200 km², 9,000 sq miles], Swaziland [17,400 km², 6,700 mi²] and The Gambia [11,300 km², 4,400 mi²]). The human population of each country also varies greatly, from about 346/km² in Rwanda to only about 2.5/km² in Namibia. With its great size and varied habitats, Africa supports a high biodiversity, including a large number of species of mammals. Likewise, most countries have a high diversity of mammals (especially when compared with temperate countries).

Africa may also be divided into biotic zones (Figure 2). A biotic zone (BZ) is defined as an area within which there is a similar environment (primarily rainfall and temperature) and vegetation, and which differs in these respects from other biotic zones. Thirteen biotic zones are recognized, two of which may be divided into smaller categories. The biotic zones exploited by each species of mammal are listed in each profile for several reasons. They indicate the environmental conditions in which the species lives and they provide data with which the geographic distribution can be explained

Figure 1. (a) Political map of Africa; (b) provinces of South Africa; (c) altitudes and major rivers of Africa. South Sudan and Somaliland are not identified as separate countries in the text.

Table 3. The countries of Africa: names, areas and human population density.

| Country name | Area
(km ²) '000 | Area
(miles ²) '000 | Human population
'000 (2006) | People per km ² |
|--|---------------------------------|------------------------------------|---------------------------------|----------------------------|
| Algeria | 2,382 | 920.0 | 33,500 | 14.1 |
| Angola (includes Cabinda) | 1,247 | 481.0 | 15,800 | 12.7 |
| Benin * [Dahomey] | 113 | 43.0 | 8,700 | 77.0 |
| Botswana [Bechuanaland] | 582 | 225.0 | 1,800 | 3.1 |
| Burkina Faso * [Upper Volta; Burkina] | 274 | 106.0 | 13,600 | 49.6 |
| Burundi [part of Ruanda-Urundi (= part of Belgian Congo)] | 27.8 | 10.7 | 7,800 | 280.5 |
| Cameroon [includes former French Cameroon, German Cameroon and part of Eastern Nigeria] | 475 | 184.0 | 17,300 | 36.2 |
| Central African Republic # | 623 | 241.0 | 4,300 | 6.9 |
| Chad [Tchad] | 1,284 | 496.0 | 10,000 | 5.8 |
| Congo [Republic of Congo] | 342 | 132.0 | 3,700 | 10.8 |
| Côte d'Ivoire * [Ivory Coast] | 322 | 125.0 | 19,700 | 61.2 |
| Democratic Republic of Congo [Belgian Congo; Congo (Kinshasha); Zaire] | 2,345 | 905.0 | 62,700 | 26.7 |
| Djibouti [French Somaliland] | 23.2 | 9.0 | 800 | 34.5 |
| Egypt | 1,001 | 387.0 | 75,400 | 75.3 |
| Equatorial Guinea # (includes Rio Muni [Spanish Guinea] and Bioko I. [Fernando Po]) | 28.1 | 10.8 | 500 | 17.8 |
| Eritrea (formerly part of Ethiopia) | 94 | 36.0 | 4,600 | 48.9 |
| Ethiopia [Abyssinia] | 1,128 | 436.0 | 74,800 | 66.3 |
| Gabon # | 268 | 103.0 | 1,400 | 5.2 |
| The Gambia | 11.3 | 4.4 | 1,500 | 132.7 |
| Ghana [Gold Coast] | 239 | 92.0 | 22,600 | 94.6 |
| Guinea * | 246 | 95.0 | 9,800 | 39.8 |
| Guinea-Bissau [Portuguese Guinea] | 36 | 13.9 | 1,400 | 38.9 |
| Kenya | 580 | 224.0 | 34,700 | 59.8 |
| Lesotho [Basutoland] | 30.4 | 11.7 | 1,800 | 59.2 |
| Liberia | 111 | 43.0 | 3,400 | 30.6 |
| Libya | 1,760 | 679.0 | 5,900 | 3.6 |
| Malawi [Nyasaland] | 118 | 46.0 | 12,800 | 108.5 |
| Mali * | 1,240 | 479.0 | 13,900 | 11.2 |
| Mauritania * | 1,030 | 412.0 | 3,200 | 3.1 |
| Morocco [includes former Spanish Morocco and French Morocco; (now also includes Western Sahara = former Spanish Sahara)] | 447 | 172.0 | 32,100 | 71.8 |
| Mozambique [Portuguese East Africa] | 802 | 309.0 | 19,900 | 24.8 |
| Namibia [South-west Africa] | 825 | 318.0 | 2,100 | 2.5 |
| Niger * | 1,267 | 489.0 | 14,400 | 11.3 |
| Nigeria | 924 | 357.0 | 134,500 | 145.6 |
| Rwanda [part of Ruanda-Urundi (= part of Belgian Congo)] | 26.3 | 10.2 | 9,100 | 346.0 |
| Senegal * | 197 | 76.0 | 11,900 | 60.4 |
| Sierra Leone | 71.7 | 27.7 | 5,700 | 79.5 |
| Somalia § [British Somaliland and Italian Somaliland; Somali Republic] | 638 | 246.0 | 8,900 | 13.9 |
| South Africa | 1,220 | 471.0 | 47,300 | 38.7 |
| Sudan § [Anglo-Egyptian Sudan] | 2,506 | 967.0 | 41,200 | 16.4 |
| Swaziland | 17.4 | 6.7 | 1,100 | 63.2 |
| Tanzania [German East Africa; Tanganyika] (now includes Zanzibar I., Mafia I. and Pemba I.) | 945 | 365.0 | 37,900 | 40.1 |
| Togo [Togoland] | 56.8 | 21.9 | 6,300 | 110.9 |
| Tunisia | 164 | 63.0 | 10,100 | 61.6 |
| Uganda | 236 | 91.0 | 27,700 | 117.4 |
| Zambia [Northern Rhodesia] | 753 | 291.0 | 11,900 | 15.8 |
| Zimbabwe [Southern Rhodesia] | 391 | 151.0 | 13,100 | 33.5 |
| Totals/mean density | 29,448 | 11,383 | 902,600 | 56.8 |

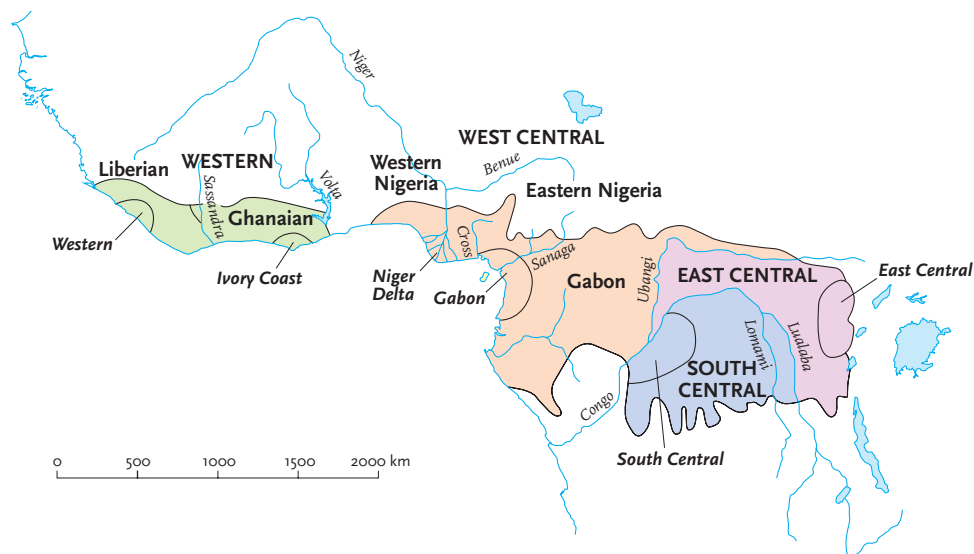

Former names are listed in chronological order in square brackets, with the oldest name listed first. Obsolete names are listed because much of the older literature refers to past colonial entities. * = formerly part of French West Africa. # = formerly part of French Equatorial Africa. § At the time of going to press, the country of Sudan had been divided into two: the Republic of Sudan in the north, and the Republic of South Sudan in the south. § The former British Somaliland is now a self-declared state under the name of the Republic of Somaliland, but remains internationally unrecognized.

Figure 2. The biotic zones of Africa.

and predicted. Furthermore, the number of biotic zones exploited by a species indicates its level of habitat tolerance and the extent to which it is vulnerable to loss of a particular type of habitat. The Rainforest Biotic Zone (Figure 3) and the South-West Arid Biotic Zone are divided into regions and subregions that reflect the different biogeographical distributions of species within the zone, each region/subregion having a community of mammals and other animals that is different to any other. Details of the biotic zones of Africa, and the regions and subregions of the Rainforest Biotic Zone, are given in Volume I of *Mammals of Africa*.

Figure 3. The Rainforest Biotic Zone showing the regions, subregions and refugia. Regions are indicated in capital letters and colours: Western region – green; West Central region – brown; East Central region – purple; South Central region – blue. Subregions are indicated in lower case letters. Refugia are indicated in lower case italics and yellow (after Happold 1996 and references therein; see also Happold & Lock, Volume I, *Mammals of Africa*).

The hedgehogs, shrews and bats of Africa

This volume is devoted to the orders Erinaceomorpha (hedgehogs), Soricomorpha (shrews) and Chiroptera (bats). These orders comprise 380 species (i.e. about 34% of all African mammals). Two of the orders contain many species – Soricomorpha (150 species) and Chiroptera (224 species) – and are the second and third most speciose orders after the Rodentia (395 species) (see Table 1). The seven orders that are considered to be the ‘small mammals of Africa’ (orders Afrosoricida and Macroscelidea [Volume I], Rodentia and Lagomorpha [Volume III], and Erinaceomorpha, Soricomorpha and Chiroptera [this volume]) collectively comprise 74.1% (827 of 1116) of all African mammalian species. Many species in the orders described in this volume have not been studied in detail because of their rarity and small geographic ranges; however, there is considerable knowledge about many of the species of bats.

There are two editors for this volume: Meredith Happold (Chiroptera; 224 species) and David C. D. Happold (Erinaceomorpha and Soricomorpha; 156 species).

The profiles for Volume IV were submitted to the editors between 2001 and 2005. It has not been possible to revise profiles since then; however, notes have sometimes been added to draw attention to important changes in taxonomy and distribution, the IUCN Categories of threat in the conservation sections have been updated, and citations of papers previously given as ‘in press’ have been completed. An Appendix has been added listing new taxa described during the period 2005–2010.

Species profiles

Information about each species is given under a series of subheadings. The amount of information under each of these subheadings varies greatly between species; where no information is available, this is recorded as ‘No information available’ or words to this effect. The sequence of subheadings is as follows:

Scientific name (genus and species) The currently accepted name of the species.

Vernacular names English, French and German names are given, as available. The first given English name is the preferred vernacular name for the species; alternative names are given in parentheses for some species. Wilson & Cole (2000) list proposed vernacular names for all the world's mammals; most of these names were also given in the third edition of *Mammal Species of the World* (Wilson & Reeder 2005). Although these works have been consulted, the names used have not always been adopted in *Mammals of Africa*. For the names of bats, there was collaboration between the authors of profiles, other bat specialists and Nancy Simmons (Simmons 2005): consequently the bat names, with very few exceptions, are the same in both publications. French names were either provided by Stéphane Aulagnier (bats), other profile authors, or taken from Gunther (2002). Most of the German names were provided by Jakob Fahr and Cornelia Rumpff (bats) and by Anke Hoffman (other taxa).

Scientific Citation This provides the full scientific name of the species, i.e. genus name, species name, authority name and date of authority. Parentheses around the authority's name and date indicate that the species was originally named in a different genus to the one it is placed in now. The scientific name is followed by the publication where the species was described, and the type locality (i.e. where the holotype [or type series] was obtained). Most of this information is taken from Wilson & Reeder (2005).

Taxonomy This section contains information about previous scientific names of the species, and problems and controversies (if any) associated with its nomenclature and relationships with other species. Major synonyms are listed (without the taxonomic authority unless essential for clarity), and the number of subspecies (usually only in Africa) is given: most of this information is from Wilson & Reeder (2005). The chromosome number is given if available,

and in some cases this is followed by other information relevant to the chromosomes. In late 2006, a revised edition of the *Atlas of Mammalian Chromosomes* was published (O'Brien *et al.* 2006), but it has not been possible to incorporate the findings of that important work here.

Description This section, together with the illustrations and relevant tables, includes sufficient information to identify the species as well as describing characters that are relevant to the habits and life-style of the species. The section begins with a brief overall description of the species, including an indication of size. (For the bats, the first sentence lists the most useful diagnostic characters of the species, ending with those that distinguish it from its most similar species.) This is followed by a more detailed description of the external characters and skulls (including the diagnostic characters); the information given covers all subspecies (if any). It was not possible – or desirable – to describe the same suite of characters for every species. Instead, an appropriate selection was made for each family and/or genus, and therefore the same suite of characters is described for all members of the relevant taxon. Consequently the descriptions of related species are comparable and compatible. The table-keys (referred to as tables in the text) function as keys to the species, and should be read from the left column to the right column, which gives the name of the species thereby identified. The number and arrangement of nipples in adult females (for taxa other than bats) is noted wherever this feature varies between the taxa being discussed (see Glossary). The tables allow easy comparison between taxa within a genus or family.

Geographic Variation Variation within the species may be clinal (without subspecies) or subspecific. If the variation is clinal, there is a description of the character(s) that alters clinally across the geographic range of the species. If the variation is subspecific, each subspecies is listed together with its geographic range and the characters that distinguish it from the other subspecies.

External characters of a hypothetical hedgehog.

External characters of a hypothetical shrew.

Similar Species A list of similar species is given together with the diagnostic characters and/or measurements most useful to distinguish that particular species from the profiled species. If a character of a similar species is described as being 'larger' or 'smaller' than that of the profiled species, there is no known overlap in the ranges of measurements of this character. In contrast, if the ranges overlap but the means are different, a character is said to be 'larger on average' or 'smaller on average'. For the Order Chiroptera, similar species are considered to be those that share a specified combination of characters, whether or not they live sympatrically. For other orders, with some exceptions, the lists of similar species are restricted to those that are sympatric or parapatric with the profiled species; this section is omitted for the genus *Crocidura* because of the very large number of species (but see Table 8).

Distribution The first sentence is often 'Endemic to Africa' indicating that the species is found (in the wild) only in Africa. Alternatively, the section begins with the distribution in Africa, and the extralimital distribution is given at the end of the section. The Biotic Zone (or Zones) in which the species has been recorded are listed because this information indicates the sorts of environments exploited by that species, and the extent to which it is likely to be threatened by habitat change. Also, it is the basis for predictions of its distribution outside the currently known limits. Next, the distribution in African countries, or parts of countries, is described, and altitudinal ranges may be given. As a general rule, descriptions of the ranges of species with very restricted distributions are more precise in terms of information given (including, for example, geographic coordinates) than for more widespread species, where a more generalized statement is adequate. A distribution map (see below) augments the information given here.

Habitat This section provides a description of the habitat, or range of habitats, where the species lives. Details of plant communities, plant species, vegetation structure, soil type and/or structure, and water availability, etc. (if available) may be recorded. Other information may include average annual rainfall, altitudinal limits and seasonal variation in habitat characteristics.

Abundance This section attempts to indicate the comparative abundance of the species. For many species, quantitative data are unavailable but the species can be assessed as 'abundant', 'common', 'rare', 'rarely seen but often heard', 'rarely collected' etc. For some species, abundance is indicated by quantitative estimates of density (e.g. number/ha or number/km²), or relative abundance within the

community (e.g. 'comprised 40% of small mammals captured', 'the second most numerous species captured'). For the better-known or rare species, actual numbers of individuals for the species may be given. Other information may include seasonal changes in density, frequency of observations, or the relative abundance of specimens in collections.

Adaptations This section describes morphological, physiological and behavioural characteristics, which show how the species uniquely interacts with its environment, with conspecifics, and with other animals. This section may also describe species-specific adaptations for locomotion, burrowing, mechanisms for orientation, production of sound, sensory mechanisms and activity patterns. It may also include descriptions of domiciles and population movements (such as migration). In some instances, comparison with related or convergent species allows the unique adaptations of the species under discussion to be detailed or emphasized.

Foraging and Food The first sentence briefly describes the diet of the species (e.g. insectivorous, carnivorous, granivorous, etc.). This may be followed by the methods of collecting food (foraging), size of home-range and daily distance moved, and descriptions of feeding behaviour. The diet, if well-known, is then described in one or more of the following ways: a list of the taxa of animals or plants consumed, a quantitative measure based on direct observations, or by a qualitative or quantitative analysis of the stomach contents or faeces.

Social and Reproductive Behaviour Topics in this section may include social organization (e.g. solitary, social or colonial), group size and composition, agonistic and amicable behaviour, territoriality and home-range (including quantitative data), courtship and mating, parental behaviour and parent–young interactions, cooperative breeding and social vocalizations.

Reproduction and Population Structure If data are available, this section describes the reproductive strategy of the species, this being determined by the litter-size and the timing of reproductive events (i.e. the reproductive chronology). Reproductive chronologies cover the times of year when spermatogenesis, ovulation, copulation, gestation, parturition and lactation occur, and consequently this indicates the duration of pregnancy and lactation, and the number of pregnancies each female may have in one year. Reproductive chronologies give data for both individuals and local populations. Special adaptations such as reproductive delays (e.g. delayed implantation) and postpartum oestrus are mentioned, and

the timing of reproductive events in relation to climatic seasons, availability of food and other relevant events are discussed. This section may also include birth-weights and sizes of young, growth-rates, age at weaning and sexual maturity, and longevity. Finally, if data are available, population structure is discussed. This includes sex ratios, adult/young ratios, the abundance of different cohorts in the population at different times of the year, and mortality rates. In general, information on reproduction is much better known for bats than for other species described in this volume.

Predators, Parasites and Diseases The known predators, known parasites (usually ectoparasites only) and some diseases are listed. Additional information is given if the species is a host to diseases that affect humans and domestic stock, and if it is utilized as food for humans ('bushmeat').

Remarks This subheading subsumes five of the above subheadings (Adaptations, Foraging and Food, Social and Reproductive Behaviour, Reproduction and Population Structure, and Predators, Parasites and Diseases) in those instances where there is little or no information available.

Conservation The conservation status of the species (i.e. its IUCN Category) is taken from the 'Red List of Threatened Species' prepared by the International Union for Conservation of Nature (IUCN). The IUCN Red List Categories follow the definitions given in the *IUCN Red List Categories and Criteria Version 3.1* (see www.iucnredlist.org) and are listed in Table 4. For those species classified as threatened (i.e. 'Vulnerable', 'Endangered' and 'Critically Endangered'), readers may obtain detailed reasons (the criteria) for the classification on the IUCN Red List website. The status of some species has been changed in recent years because

of improved knowledge, changes in taxonomy, or the impact of threatening processes or conservation action; detailed reasons for the present status, and past status, are given on the IUCN Red List website. If a species is listed on an Appendix I or Appendix II under CITES (Convention on International Trade in Endangered Species; www.cites.org), this is also indicated. For some species, additional information is provided, such as presence in protected areas, major threats, and current or recommended conservation measures.

Measurements A series of morphological measurements is provided. For each species in a particular order there is a standard set of measurements. The abbreviation (and definition) for each measurement are given in the Glossary. A measurement is cited as the mean value (with minimum value to maximum value in parentheses) and sample size. For some, the standard deviation (mean \pm 1 S.D.) is given instead of, or in addition to, the range. For most measurements, data for males and females are combined but where there is sexual dimorphism, measurements for males and females are given separately. Where possible, the localities of the measured specimens and the source of the data are provided. Sources are either cited publications, or specimens in museums, or unpublished information from the authors or others. The acronyms for museums where specimens were examined and measured are given in Table 5. Most museum records have been provided by the author of the profile; others – when an author did not have the measurements or did not have the opportunity to visit museums – were provided by the editors.

Key References A select list of references provides more information on the species. Each reference is given in full in the Bibliography.

Table 4. IUCN Red List Categories (from IUCN – International Union for Conservation of Nature).

| Category | Description |
|-----------------------------------|--|
| Extinct (EX) | A taxon is Extinct when there is no reasonable doubt that the last individual has died. A taxon is presumed Extinct when exhaustive surveys in known and/or expected habitat, at appropriate times (diurnal, seasonal, annual), throughout its historic range have failed to record an individual. Surveys should be over a time frame appropriate to the taxon's life-cycles and life form. |
| Extinct in the Wild (EW) | A taxon is Extinct in the Wild when it is known only to survive in cultivation, in captivity or as a naturalized population (or populations) well outside the past range. A taxon is presumed Extinct in the Wild when exhaustive surveys in known and/or expected habitat, at appropriate times (diurnal, seasonal, annual), throughout its historic range have failed to record an individual. Surveys should be over a time frame appropriate to the taxon's life-cycle and life form. |
| Critically Endangered (CR) | A taxon is Critically Endangered when the best available evidence indicates that it meets any of the criteria A to E for Critically Endangered, and it is therefore considered to be facing an extremely high risk of extinction in the wild. |
| Endangered (EN) | A taxon is Endangered when the best available evidence indicates that it meets any of the criteria A to E for Endangered, and it is therefore considered to be facing a very high risk of extinction in the wild. |
| Vulnerable (VU) | A taxon is Vulnerable when the best available evidence indicates that it meets any of the criteria A to E for Vulnerable, and it is therefore considered to be facing a high risk of extinction in the wild. |
| Near Threatened (NT) | A taxon is Near Threatened when it has been evaluated against the criteria but does not qualify for Critically Endangered, Endangered or Vulnerable now, but is close to qualifying for (or is likely to qualify for) a threatened category in the near future. |
| Least Concern (LC) | A taxon is Least Concern when it has been evaluated against the criteria and does not qualify for the Critically Endangered, Endangered, Vulnerable or Near Threatened categories. Widespread and abundant taxa are included in this category. |
| Data Deficient (DD) | A taxon is Data Deficient when there is inadequate information to make a direct, or indirect, assessment of its risk of extinction based on its distribution and/or population status. Data Deficient is not a category of threat. Listing of taxa in this category indicates that more information is required and acknowledges the possibility that future research will show that a threatened classification is appropriate. |
| Not Evaluated (NE) | A taxon is Not Evaluated when it has not yet been evaluated against the criteria. |

Author The name of the author, or authors, is given at the end of each profile. All profiles should be cited using the author name(s).

Tables For selected taxa (mainly families and genera) tables (sometimes in the form of table-keys) provide details of the main characteristics of these taxa and can be used as an aid to identification. The tables were prepared by the editors.

Higher order profiles

The profiles for orders, families and genera are less structured than for the species profiles. Each profile usually begins with a listing of the taxa in the next lower taxon; for example, each family profile lists the genera in that family. An exception to this arrangement is where a taxon has only one lower taxon. Higher taxa profiles provide the characteristics common to all members of that taxon. Some of these characteristics may not be repeated in lower taxon profiles (unless essential for identification) so readers are encouraged to consult also the next higher taxon profile, e.g. the species profile for *Crocridura olivieri* should be consulted in association with the genus

Crocridura profile. For the Chiroptera, the higher taxon profiles end with information that enables readers to recognize and distinguish the next lowest taxa (e.g. family profiles end with the diagnostic characters of the genera in that family).

Distribution maps

Each species profile, with a very few exceptions, contains a pan-African map showing the geographic range of the species. Most maps were provided by the author of the profile and were compiled from literature records and museum specimens; some maps were provided by the editor(s) when it was not possible for the author to do so. Each map shows the boundaries of the 47 countries of Africa, some of the major rivers (Nile, Niger–Benue, Congo [with the tributaries Ubangi, Lualaba and Lomani], Zambezi and Orange), and Lakes Chad, Tana, Turkana (formerly Rudolf), Albert, Edward, Victoria, Kyoga, Kivu, Tanganyika, Malawi, Mweru, Bangwuela and Kariba. The map projection is 'Transverse Mercator, with the following parameters: False Easting: 0; False Northing: 0; Central Meridian: 20; Linear Unit: metre; Datum: Clarke 1866'. The geographic

distribution of a species is indicated as:

- red shading = current range(s).
- × = individual localities when only a few localities are known, or isolated localities considered to be separate from the main geographic range(s). Some localities indicated by × may include two or more closely spaced localities.
- ? = locality of uncertain validity; relevant information usually in text.
- red arrow = recorded from the island indicated by the arrow.

Order ERINACEOMORPHA – Hedgehogs

Erinaceomorpha Gregory, 1910.

| | | |
|-----------------------------------|-----------------|-------|
| Erinaceidae (3 genera, 6 species) | Spiny Hedgehogs | p. 29 |
|-----------------------------------|-----------------|-------|

The order Erinaceomorpha contains one family, ten genera and 20 species, distributed throughout Eurasia and Africa (Corbet 1988, Reeve 1994). The single family contains two subfamilies: the Galericinae (the Gymnures or Hairy Hedgehogs) and the Erinaceinae (the Spiny Hedgehogs). The five genera and six species of Hairy Hedgehogs live in the temperate and tropical forests of Asia, and are not considered further in this account. The Spiny Hedgehogs – usually referred to as just ‘Hedgehogs’ – occur widely in temperate Eurasia and Africa; currently, they are classified into five genera and 14 species, of which six species (in two or three genera) live in Africa.

The order (as family Erinaceidae) was previously included within the order Insectivora (Hutterer 2005a). Although the name Erinaceomorpha is not new – it was originally proposed by Gregory in 1910 – recent research has indicated that the Insectivora (hedgehogs and moonrats, shrews, moles, golden-moles, otter-shrews and tenrecs) are not a closely related group, and that the order Insectivora should be divided into three orders – Erinaceomorpha (hedgehogs and moonrats), Soricomorpha (shrews and moles) and Afrosoricida (golden-moles, otter-shrews, tenrecs). The following account deals only with the African hedgehogs – the sole representatives of the Erinaceomorpha in Africa.

The two best known characteristics of hedgehogs are their short pointed spines, which densely cover all of the back and flanks, and their ability to curl up into a ball when disturbed. Each spine is thought to be the equivalent of several hairs, where the follicles have coalesced, rather than of a single hair. The spines grow in lines, each spine pointing outwards in a slightly different direction; this results in a dense mat of spines that point in all directions. The spines are shed and replaced, just like normal hairs but more slowly. Hedgehogs can curl into a ball so that the head, limbs, tail and ventral surface are protected by the spiny back and flanks. Under the spiny skin are two large muscles, the orbicularis and panniculus carnosus, which encircle the back, chest and flanks forming a hood-like structure over the animal. Other muscles run downwards from the orbicularis and overlie the forehead, shoulders and rump; when a hedgehog is disturbed, these muscles contract very rapidly pulling the orbicularis downwards. At the same time, the orbicularis itself contracts and the whole body becomes enveloped within the stretched panniculus muscle. This movement stretches the very flexible skin and causes the spines to erect, providing additional protection (Reeve 1994). Hedgehogs can remain in this state for hours on end; they also roll up (but not so tightly) when asleep or in torpor and hibernation. Hedgehogs are characteristically parasitized by many fleas, which may be observed frequently among the spines.

Hedgehogs are small mammals, weighing on average 130–205 g as adults (African species). They are compact, rotund little animals because the neck, tail and limbs are short. The head is broad, the snout is slightly elongated and mobile, and the well-developed sense of smell is used for locating prey. The eyes are of moderate

size but sight is primarily monochrome and highly developed. The ears vary from being quite small to very large, and hearing is very acute; some desert species have enlarged auditory bullae (as do some desert rodents), which enhances detection of very quiet noises in open spaces. Olfaction and hearing are the dominant senses for hedgehogs. The skull is strongly built with wide zygomatic arches so that the head appears rather broad. The dental formula is $I^{3/2}, C^{1/1}, P^{3/2}, M^{3/3} = 36$. The teeth are similar in structure and function to other small species of insectivores. One of the upper incisors is long and caniform, and points anteriorly. The canine teeth are small, as are the front premolars. The last premolar and the molars are large with well-developed pointed cusps that crush and slice through the exoskeletons of arthropod prey.

Hedgehogs live in a very wide range of habitats from cold temperate steppes to hot tropical savannas. In the cooler parts of their range (where sub-zero temperatures, frosts and snow occur in winter), they enter hibernation (see below). In the hotter parts of their range, they may be active all year, but may enter torpor during the dry season when food is scarce. Unlike many mammals, they adapt to human-modified environments and may be common (but rarely seen) in towns, cities and gardens. They do not live in rainforests or in very dry deserts. Although sometimes considered as rather ‘primitive’ mammals with rather few species, their widespread distribution and adaptability show that, as a family, they are very successful.

Hedgehogs are terrestrial, although some species are scansorial and can climb over logs and fences. They have short limbs, each with four or five digits ending in claws. They walk or trot on the soles of the feet, and can move surprisingly quickly for their size. They are nocturnal and active during most of the night, usually with peaks of activity before midnight and around 03:00h. During the day, they rest in a variety of habitats – under logs and piles of stones, in caves and rocky crevices, and in dense litter and hedgerows; some species dig burrows or rest in the burrows made by other animals. Surprisingly, most species can swim.

Hedgehogs are omnivorous, but their preferred prey is arthropods (mainly insects), earthworms, snails, small reptiles and eggs. Some species eat fruits and fungi in season. They appear to be resistant to toxins produced by some of their prey (such as centipedes and bees). When food is abundant, hedgehogs store fat under the skin and around some organs, and increase in weight. Fat is utilized (and weight declines) when food is scarce during the colder and drier months of the year.

Hedgehogs have the ability to change their metabolic rate in relation to environmental conditions. When the climate is cool or cold (and food may be limited), hedgehogs lower their metabolic rate and reduce their body temperature, and enter a state known as torpor or hibernation. The ability to hibernate is well understood and documented in temperate species, but it appears that African species enter torpor during the cold season of North Africa and South Africa, and during the dry season of tropical Africa. Torpor is physiologically different to hibernation and the metabolic rate

does not decline to the same extent, but it does enable individuals to reduce their energy expenditure and heat loss when environmental conditions are unfavourable.

African hedgehogs, like temperate ones, are mostly solitary. Very little is known about their behaviour and social organization in Africa. Likewise, little is known about their reproduction in the wild; the few observations that are available suggest that birth of young in most localities is seasonal. There are usually 2–6 young in a litter, and growth is rather slow. Most individuals probably do not breed until they are about a year old.

In Africa, fossil remains of hedgehogs are known from the early Miocene (Yates 1984). All the extant species of African hedgehogs are rather similar, but each of the six species has radiated into a different environment. The species are essentially allopatric with very limited overlap in their geographical ranges. African hedgehogs are found throughout the continent except in the Rainforest BZ and the driest parts of the Sahara and South-West Arid BZs.

D. C. D. Happold

Table 6. Characteristics of species in the family Erinaceidae in Africa. See also Figure 5.

| Species | Mean HB (mm) | Central parting of spines | Surface of spines | Face-mask | Digit 1 on hindfoot | Ears (length as % of HF) | |
|--------------------------------|--------------|---------------------------|--|---|------------------------------|--|--|
| <i>Atelerix albiventris</i> | 167 | Narrow | Smooth | Black; well defined, slight posterior extension on to lower cheek | Absent (or very rudimentary) | Small, rounded, shorter than adjacent spines (73%) | |
| <i>Atelerix algirus</i> | ca. 235 | Narrow | Smooth | None; black 'spotting' on muzzle in some individuals | Small | Small, rounded, shorter than adjacent spines (77%) | |
| <i>Atelerix frontalis</i> | ca. 190 | Narrow | Smooth | Black or dark brown; well defined, extends ventrally to merge with black ventral pelage | Small | Small, rounded, shorter than adjacent spines (76%) | |
| <i>Atelerix sclateri</i> | 225 | Narrow | Smooth | Black; well defined, extends slightly on to cheek | Small | Small, rounded, shorter than adjacent spines (88%) | |
| <i>Hemiechinus auritus</i> | 179 | Absent | Papillate with fine longitudinal grooves | None | Large | Large, considerably longer than adjacent spines (114%) | |
| <i>Paraechinus aethiopicus</i> | 196 | Wide | Papillate with fine longitudinal grooves | Black; well defined | Large | Large, slightly pointed, protrude above adjacent spines (132%) | |

Family ERINACEIDAE

HEDGEHOGS

Erinaceidae G. Fischer, 1817. Mem. Soc. Imp. Nat., Moscow, 5: 372.

| | | |
|--------------------------------|---------------------|-------|
| <i>Atelerix</i> (4 species) | Hedgehogs | p. 30 |
| <i>Hemiechinus</i> (1 species) | Long-eared Hedgehog | p. 37 |
| <i>Paraechinus</i> (1 species) | Ethiopian Hedgehog | p. 39 |

The family Erinaceidae occurs widely in temperate Eurasia and Africa; currently, they are classified into five genera and 14 species. Characteristics of the family are given in the order profile above.

African hedgehogs are placed in three genera, *Atelerix*, *Hemiechinus* and *Paraechinus* (Figure 4). *Atelerix* has been considered as a subgenus of *Erinaceus* (Corbet 1974a, Yates 1984), which contains several species of European and temperate Asian species, but Robbins & Setzer (1985) showed that it warrants generic distinction (see also Hutterer 2005a). The genera are distinguished by many characters (Figure 5, Table 6), the most important being the presence or absence of a central parting between the spines of the scalp (and if present, its comparative width), the presence or absence of papillae on the spines, the size of the ears and their size relative to the length of the adjacent spines, the form of some of the teeth, the width and form of the palatal shelf, the form of the auditory bullae and (in ♂♂)

Atelerix albiventris.

the structure of the glans penis (Corbet 1988). Compared with the European Hedgehog *Erinaceus europaeus*, there are few detailed studies on African hedgehogs, especially in the wild.

African hedgehogs range in size (mean HB) from 167 mm to ca. 235 mm. Species are considered as ‘small’ (mean HB of <180 mm), ‘medium-sized’ (mean HB 180–200 mm) or ‘large’ (mean HB >201 mm). Ear length is considered as ‘small’ (<30 mm) or ‘large’ (>30 mm) (see Table 6).

Hemiechinus auritus.

Paraechinus aethiopicus.

Figure 4. The three genera of African hedgehogs.

| | Colour of ventral pelage and limbs | Number of roots on premolar | Notes |
|--|---|-----------------------------|--|
| | White; limbs pale | 2 | Widespread in savanna and semi-arid. Senegal to Ethiopia; E Africa north of Zambezi R. |
| | White; limbs pale | 3 | Morocco to Libya north of Sahara |
| | Grey to black; limbs grey to black | 2 or 3 | Southern Africa only |
| | White or buffy-white; limbs dark | 2 (barely divergent) | Somalia |
| | White; limbs long, white | 1, 2 (barely divergent), 3 | Egypt and Libya |
| | White, dark posteriorly; limbs long, dark brown | 1 | Sahara Desert and surrounding semi-arid regions |

The genera are distinguished by the presence/absence of the central parting on the forehead, whether the spines are papillate or smooth, and the width of the palatal shelf.

D. C. D. Happold

Figure 5. External characters of African hedgehogs: *Atelerix* (left), *Hemiechinus* (centre) and *Paraechinus* (right). (a) Head showing parting and face-mask. (b) Left hindfoot. (c) Section of spine. After Corbet (1988).

GENUS *Atelerix* Hedgehogs

Atelerix Pomel, 1848. Arch. Sci. Phys. Nat. Geneve 9: 251. Type species: *Erinaceus albiventris* Wagner, 1841.

The genus *Atelerix* contains four species endemic to Africa, which occur throughout the savanna regions of the continent. All species in the genus have a narrow parting of the spines on the head, smooth spines (without papillae), rather small ears, broad palatal shelf and small auditory bullae (Figure 6). The hallux (Digit 1 of hindfoot) is

small or absent. The genus *Atelerix* has often not been recognized, and the four species have been included within the genus *Erinaceus* (which includes three species very widely distributed in the Palearctic regions). However, multivariate analysis of cranial characteristics (Robbins & Setzer 1985) as well as other non-cranial characters

Atelerix albiventris.

Atelerix sp.

Figure 6. Skull and mandible of *Atelerix frontalis* (BMNH 34.10.10.213).

Atelerix albiventris.

and distribution patterns, clearly warrant separation of the African species in a separate genus (Corbet 1988, Hutterer 2005a). The four species are allopatric; one species – *A. albiventris* – is very widespread in central, East and West Africa, and the other species have more limited geographic distributions.

The species are distinguished by presence/absence of face-mask, colour of ventral pelage, presence/absence of Digit 1 on hindfoot, body size and geographic distribution (see Table 6).

D. C. D. Happold

Atelerix albiventris WHITE-BELLIED HEDGEHOG (FOUR-TOED HEDGEHOG)

Fr. Hérisson à ventre blanc; Ger. Weissbauchigel

Atelerix albiventris (Wagner, 1841). In Schreber. Die Säugethiere, Suppl. 2: 22. Probably Senegal or Gambia.

Taxonomy Originally described in the genus *Erinaceus*. The species, as now understood, includes many taxa originally considered to be species and subspecies; all are now treated as synonyms. Synonyms: *adansoni*, *atratus*, *diadematus*, *faradjius*, *heterodactylus*, *hindei*, *kilimanus*, *langi*, *lowei*, *oweni*, *pruneri*, *sotikae*, *spiculus*, *spinifex*. Subspecies: none recognized here; the large variation within populations suggests that subspecific differentiation is not justified (Corbet 1988, Reeve 1994). Chromosome number: $2n = 48$, $aFN = 96$ (Hübner *et al.* 1991).

Description Small hedgehog with four digits on hindfoot. Dorsal pelage of dark spines; spines 15–20 mm, basal half off-white, terminal half dark brown or blackish-brown, often with white tip. Considerable variation in banding pattern on spines. Surface of spines smooth without papillae. Ventral pelage of non-spiny hairs; rather sparse; hairs white or buffy-white. Spiny dorsal pelage and hairy ventral pelage clearly delineated on lower flanks. Head with wide white forehead from cheek to cheek; narrow central parting of spines on crown of head; face-mask on muzzle and around eyes black, well-defined, extending posteriorly on lower cheek (see also below). Ears small, rounded, shorter than adjacent spines; ca. 73% of HF. Limbs short, white or pale; forefeet with

five digits; hindfeet with four digits, Digit 1 absent or rudimentary. Tail relatively very short (ca. 7% of HB), barely visible, with small pale hairs. Nipples: not known. Glans penis without spiny or papillate pads. Some ♂♂ tend to be larger and heavier than ♀♀. Skull: auditory bullae comparatively small (see Measurements); P^3 with two roots. See Table 6.

Geographic Variation Specimens from drier habitats appear paler because they have a greater number of white-tipped spines; some individuals do not have a black face-mask.

Similar Species

Paraechinus aethiopicus. On average larger (HB: 196.1 [169–217] mm); wide central parting on crown; spines with papillae and grooves; ears much longer (41–45 mm), longer than adjacent spines; hindfeet with five digits; Sahara and northern semi-arid regions.

Atelerix sclateri. On average larger (HB: 225.0 [210–263] mm); Digit 1 of hindfoot present, small but not rudimentary; Somalia only.

A. frontalis. On average slightly larger (HB (♂♂): 185 [170–190] mm, HB (♀♀): 196 [186–210] mm); face-mask extending ventrally to merge with black ventral pelage; south of Zambezi R. only.

Distribution Endemic to Africa. The most widespread of the African hedgehogs. Recorded from Sudan Savanna and Guinea Savanna BZs, Northern and Eastern Rainforest–Savanna Mosaics and most of the Somalia–Masai Bushland BZ. Penetrates the northern margins of the Rainforest BZ where habitat destruction has created grasslands and cultivations. Recorded from Senegal to Ethiopia, Djibouti and Somalia, and southwards through East Africa to Zambia (north of the Zambezi R.) and Malawi. Only known overlap in geographic range with other species of hedgehogs is with *Paraechinus aethiopicus* in C Sudan and N Ethiopia (and possibly at other places where the northern savannas meet the Sahara Desert), and with *A. sclateri* in N Somalia. (Note: the record of this species from Liberia [Lienhardt 1982] is presumably an error.)

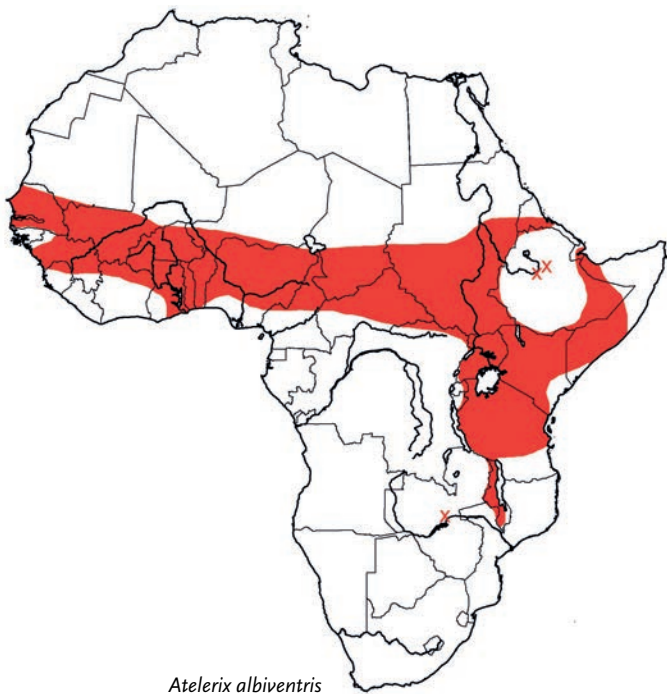

Habitat Savanna and semi-arid habitats, including rocky inselbergs. Tends to avoid waterlogged habitats, marshes and swamps. Often found in suburban gardens and cultivated fields.

Abundance May be common in suitable habitats. Individuals are seen more often at the beginning of the wet season when more individuals are killed by vehicles on roads.

Adaptations Nocturnal and terrestrial. During day, rests under rocks and logs, and in crevices and termitaria. In captivity, two peaks of nocturnal activity are evident: 21:00–24:00h and around 03:00h (Herter 1965). When active, hedgehogs walk and trot on all four limbs.

Body temperature (T_b) is maintained at 32.9–35.4 °C at normal ambient temperatures (Herter 1971). In captivity, when T_a is 19–24 °C, individuals become torpid and less active than normal. A similar drop in T_b is likely to occur in those regions where cool nights are experienced at some times of the year.

Foraging and Food Detailed information unavailable; probably similar to other species of hedgehogs (see order and family profiles).

In East Africa, the diet is reported to consist of earthworms, snails, slugs, crabs, fruit, fungi, roots and groundnuts (Kingdon 1974). Hedgehogs usually forage alone.

Social and Reproductive Behaviour Primarily solitary. Several vocal sounds are emitted, which enable communication between individuals and express mood. Five categories of audible vocal sounds have been recorded (Gregory 1975). (1) Twitter – a very quiet sound emitted through the closed mouth, and often accompanied by sniffing; usually associated with unfamiliar situations. Each twitter is of very short duration (5–40 msec) and several are emitted in pulses lasting for several seconds. (2) Hiss – a short noise of lower pitch than the twitter, emitted during stressful situations. (3) Snort – similar to the hiss, but louder and emitted when severely stressed or attacked, often repeated rapidly. (4) Scream – a rare sound, emitted under extreme stress. (5) Serenade – a series of low-pitched sounds ranging from a pure whistle to a course squawk, emitted by ♂♂ during courtship behaviour.

The faecal pellets have a strong odour, and may be a means of advertising the presence of an individual. Likewise, 'self-anointing' (licking the spines of the flank with copious amounts of saliva) may be a means of advertising and ensuring recognition (Reeve 1994).

Courtship behaviour is said to be similar to that of the European Hedgehog *Erinaceus europaeus* (M. W. Gregory, in Reeve 1994). When the ♂ approaches, the ♀ reacts aggressively, bristling her spines and snorting. The ♂ attempts to circle the ♀, who may try to run away; the ♀ responds by vigorously pushing the ♂ on his flank with the spines on her head. Such behaviour may last for minutes or hours. Copulation occurs when the ♂ mounts the ♀ from behind; the ♂ has a particularly long penis, perhaps because the spines on the rump of the ♀ prevent him from getting too close to the ♀.

Reproduction and Population Structure Times of reproductive activity vary in different parts of the range: probably active all year in East Africa (Kingdon 1974), but seasonal in drier and cooler habitats. Collections in Nairobi for a complete year include the following: pregnancies in Jul and Aug; litters in Apr–May; juveniles (<200 g) in Jan, Feb, Mar, Apr, May, Jun and Jul (Gregory 1976). Gestation: 35–37 days. Litter-size in captivity: 3.1 (1–6), $n = 52$ litters (1 young [$n = 8$], 2 [$n = 14$], 3 [$n = 11$], 4 [$n = 6$], 5 [$n = 9$], 6 [$n = 4$]). Young altricial at birth; WT: 5–11 g. Increase in weight is rapid: 25 g by Day 7, 50 g by Day 13, 70–75 g by Day 20, 110–120 g by Day 28, 130–150 g by Day 34, 170–190 g by Day 40 (Brodie *et al.* 1982, Lienhardt 1982). Maturity attained in ca. 5–6 months, but in the wild young probably do not breed until the next breeding season, when about one year old. Young are blind and naked at birth.

Predators, Parasites and Diseases The spines provide good protection against predators; however, remains of this species have been found in the pellets of Giant Eagle-owls *Bubo lacteus* in East Africa (Brown 1965) and in Nigeria (Happold 1987). In some parts of their geographical range, hedgehogs are eaten by humans, and they are vulnerable to being killed by vehicles on roads. In East Africa, the skin and spines are sometimes used as fertility charms.

Many ectoparasites have been recorded from hedgehogs in Kenya, Nairobi and Sudan, including fleas (*Ctenocephalides felis*, *C. crataepus*,

Echidnophaga gallinacea, *Xenopsylla cheopis*), ticks (*Haemophysalis leachi*, *H. spinulosa*, *Rhipicephalus sanguineus*, *R. simus*) and mites (*Caparinia erinacei*, *Notoedres oudemansi*, *Rodentopus sciuri*, *Sarcoptes scabiei*) (Gregory 1981, Okaeme & Osakwe 1985, Reeve 1994). Hedgehogs are also hosts to endoparasites; in Nairobi many hedgehogs were parasitized by tapeworms, nematodes and acanthocephalines (Gregory 1981).

Conservation IUCN Category: Least Concern.

This widespread species is unlikely to be threatened at present.

D. C. D. Happold

Atelerix algirus ALGERIAN HEDGEHOG

Fr. Hérisson d'Algérie; Ger. Algerischer Igel

Atelerix algirus Lereboullet, 1842. Mem. Soc. Hist. Nat. Strasbourg 3 (2), art. QQ: 4. Oran, Algeria.

Taxonomy Synonyms: *caniculus*, *fallax*, *girbaensis*, *lavaudeni*, *vagans*. Subspecies: none recognized here. Several have been described for mainland and introduced island populations (see below); the insular populations show variation in pelage colouration but subspecific recognition is considered unwarranted by Corbet (1988). In contrast, Hutterer (2005a) recognizes *girbaensis* and *vagans* as subspecies. Chromosome number: not known.

Description Large hedgehog with five digits on hindfoot. Dorsal pelage of dark spines often with some pure white spines. Surface of spines smooth and without papillae. Ventral pelage of non-spiny hairs; hairs white or buffy-white, sometimes with dark patches. Spiny dorsal pelage and hairy ventral pelage clearly delineated on lower flanks. Head with wide white forehead from cheek to cheek; narrow central parting of spines on crown of head; muzzle white without dark face-mask (or with only a slight 'spotting' of dark hairs). Ears small, rounded, shorter than adjacent spines; ca. 77% of HF. Limbs short, white or pale; forefeet with five digits; hindfeet with five digits, Digit 1 may be slightly shorter than other digits. Tail relatively very short (<10% of HB), barely visible, with small pale hairs. Glans penis without spiny or papillate pads, expands laterally. Skull: auditory bullae moderate size; P³ with three roots. Nipples: not known. See Table 6.

Geographic Variation Individuals from Morocco are paler than those from Algeria, Tunisia and Libya (Corbet 1988).

Similar Species

Paraechinus aethiopicus. Wide central parting on crown; spines with papillae and grooves; black face-mask; ears longer than adjacent spines; Sahara and northern semi-arid regions.

Hemiechinus auritus. No central parting on crown; spines with papillae and grooves; no face-mask; ears very large, much longer than adjacent spines; Egypt and Libya only.

Distribution Endemic to Africa. Mediterranean Coastal BZ and (infrequently) coastal regions of the Sahara Arid BZ. Recorded

from Morocco, Algeria and Tunisia between the Mediterranean coast and the semi-arid habitats north of the Sahara Desert, including the Atlas Mts. In Libya, occurs only in a few localities near the coast, as far west as Cyreniaca. Djerba Is. (Tunisia). Introduced into several islands of the Balearic and Canary Is., and into parts of the Mediterranean coastal regions of France and Spain. Overlaps marginally with *Paraechinus aethiopicus* in the southern part of its range.

Habitat Mediterranean scrublands and grasslands, cultivations, palm groves and suburban gardens. May occur up to 2000 m in the Middle Atlas of Morocco (Aulagnier & Thévenot 1986).

Atelerix algirus

Abundance Common in cultivated regions and palm groves (Aulagnier & Thévenot 1986). In Libya, more abundant than the other two species of hedgehogs (*P. aethiopicus* and *H. auritus*).

Adaptations Nocturnal and terrestrial. It seems likely that Algerian Hedgehogs enter torpor during the winter.

Foraging and Food Primarily insectivorous and opportunistic; the diet includes worms, eggs and fruits (Aulagnier & Thévenot 1986), snails and insects (Hufnagl 1972). Introduced animals in the Balearic Is. are reported to feed on snails, centipedes, insects, snakes, lizards and a truffle-like fungus (J. A. Alcover, in Corbet 1988).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Reproduction appears to be limited to spring and summer. In Libya, breeding occurs from Apr to Jun, and occasionally a second litter is produced in Jul. Gestation: 30–48 days; litter-size: 3–7. Young remain close their mother for several months (Hufnagl 1972).

Predators, Parasites and Diseases Remains are infrequently found in owl pellets in Algeria (Kowalski & Rzebik-Kowalska 1991). May be eaten by humans in the Balearic Is. (Corbet 1988). Frequently killed by vehicles on roads in all parts of its range. Ectoparasites

include the flea *Echidnophaga gallinacea* (also found on chickens); endoparasites include nematode worms (Reeve 1994).

Conservation IUCN Category: Least Concern.

D. C. D. Happold

Atelerix frontalis SOUTHERN AFRICAN HEDGEHOG

Fr. Hérisson du Cap; Ger. Kap-Igel

Atelerix frontalis (A. Smith, 1831). S. Afr. Quart. J., ser. 1, 5: 10. N Graaff Reinet district, South Africa.

Taxonomy Originally described in the genus *Erinaceus*. Synonyms: *angolensis*, *capensis*, *diadematus*, *fractilis*. Subspecies: two of uncertain validity. Chromosome number: not known.

Description Medium-sized hedgehog with five digits on hindfoot. Dorsal pelage of dark spines; spines white at base, with broad black or dark-brown subterminal bands and white or buffy tip. Surface of spines smooth without papillae. Ventral pelage of non-spiny hair, dark grey, brown or black. Head with white forehead; narrow central parting of spines on crown of head; black or dark brown face-mask on muzzle and around eyes extending posteriorly and ventrally to merge with the dark colouration on throat and chest (Figure 4). Ears small and rounded, shorter than adjacent spines; ca. 76% of HF. Limbs short, grey-brown to dark brown; hindfeet with five digits. Tail relatively very short (ca. 15% of HB). Nipples: 2 + 1 = 6. Skull: auditory bulla comparatively small.

Geographic Variation Shortridge (1934) and Meester *et al.* (1986) list two subspecies without comment:

A. f. angolae: SW Angola, N and C Namibia.

A. f. frontalis: W and C Zimbabwe, E Botswana and South Africa.

Similar Species

Atelerix albiventris. Ventral pelage white or buffy-white; four digits on

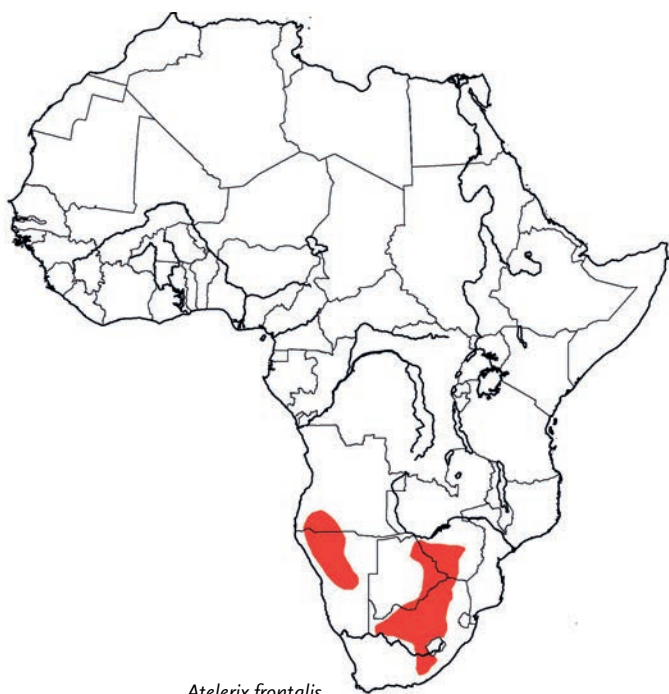

HF; widespread in savanna habitats south of the Sahara and north of the Zambezi R. Allopatric.

Distribution Endemic to Africa, Zambezian Woodland BZ (SE and SW parts), Highveld BZ and parts of South-West Arid BZ (Karoo). Distribution disjunct with two separate ranges: (a) SW Angola, and N and C Namibia; (b) W and C Zimbabwe, E Botswana, and South Africa west of 31°E and southwards towards Grahamstown and the eastern Karoo (Smithers 1968, Rautenbach 1982, Lynch 1983, Skinner & Smithers 1990). Not recorded north of the Zambezi R. or from Swaziland (Monadjem 1998c) or KwaZulu–Natal (Taylor, P. 1998). Geographic range not known to overlap with *Atelerix albiventris*.

Habitat Occurs in many habitats in semi-arid and sub-temperate regions where annual rainfall is 300–800 mm and where there is ample ground cover. Not found in deserts or mesic habitats. Regularly found in suburban gardens.

Abundance Generally uncommon or rare (Shortridge 1934, Smithers 1983); tend to be commoner in suburban gardens where there is cover and food. In South Africa, numbers have declined with increased usage of domestic and agricultural pesticides.

Adaptations Terrestrial. Southern African Hedgehogs spend the day curled up in a ball under the cover of vegetation or in holes

Atelerix frontalis

in the ground, emerging in the evening to forage. Locomotion is slow, but agile when in flight. They are predominantly nocturnal, but exhibit some diurnal activity after rain has fallen, probably to feed on emerging earthworms.

Southern African Hedgehogs enter torpor during the cool dry season (= winter) when T_a is low. Torpor is characterized by low oxygen consumption, low respiration rate and a lowered body temperature. Experimental study has shown that at 15 °C and a 10 : 14 hour light : dark photoperiod, hedgehogs readily enter torpor. Similarly, on a restricted diet (about 40% of weekly maximum consumption) they display longer periods of torpor (Gillies *et al.* 1991). During torpor, fat reserves accumulated during the wet season are utilized to obtain energy (Smithers 1983). It appears that hedgehogs can modify the length of torpor in response to the availability of food and energy.

The timing and duration of torpor is likely to vary geographically. In the colder regions of the geographic range (eastern Free State, South Africa) where ambient temperatures fall to -9 °C during the winter, hedgehogs are inactive and remain in their burrows from Jun to Aug. During this period, there may be a 11–19% loss of body weight. If there is a warm spell during winter, hedgehogs may emerge and feed briefly before resuming torpor again (Smithers 1983). Torpor ends when temperatures increase in spring (Sep).

The dorsal spines are an effective means of defence when accompanied by rolling into a ball with the head, limbs and soft ventral surface in the centre. Smithers (1983) reported the sighting of a Lion *Panthera leo* in Hwange N. P., Zimbabwe, which was rolling a balled hedgehog between its paws and trying to bite it; the hedgehog survived and was none the worse for the encounter!

Foraging and Food Omnivorous. Hedgehogs forage in litter and just under the soil surface, and food is located mainly by scent. The diet includes variety of invertebrates such as beetles, earwigs, grasshoppers, termites, slugs and snails (which form the bulk of their diet) and small vertebrates such as small mammals, eggs and chicks

of terrestrial birds, frogs and lizards. Some vegetable matter (e.g. fungi) may also be eaten. In captivity, hedgehogs eat invertebrates, minced beef, bread and dogfood (Smithers 1966, Smithers & Wilson 1979, Lynch 1989, Skinner & Smithers 1990). They do not seem to be dependent on free water, which is often not available, or available only seasonally, in their preferred habitat.

Social and Reproductive Behaviour Usually solitary, but also recorded in pairs and as a ♀ with young (Lynch 1983). Aggressive behaviour includes head butting accompanied by vocalizations that have been described as snuffling, snorting and growling. The alarm call is a high-pitched screech (Smithers 1983).

Females give birth to young in sheltered nests in debris or in holes lined with dry leaves. In the Free State, South Africa, they sometimes utilize termitaria for nesting (Lynch 1983). The young remain in or around the nest for 4–6 weeks after birth, and then can be seen foraging in the company of the ♀. Males do not participate in parental care (Skinner & Smithers 1990).

Reproduction and Population Structure Reproduction occurs during the warm wet summer months (Oct–Apr), and ♀♀ are seasonally polyoestrous. Gestation: 5–6 weeks. Litter-size: usually four (range 1–9; Smithers 1983). At birth: 5 cm in length, WT: 9 g, blind and hairless, ears closed, and rudimentary spines visible beneath skin. Development of spines is rapid; tips of unpigmented spines emerge through skin 1–3 h after birth and lengthen to about 6.5 mm by Day 2. Pigmented spines appear on Day 3, and by Day 7 a distinctly hedgehog-like appearance is attained and characteristic behaviour described as frowning, puffing and jerking is evident. Eyes open Day 10. Infant spines shed at 4–6 weeks. Weaned at about five weeks (Jacobsen 1982). A ♀ may produce more than one litter each year (Skinner & Smithers 1990).

Predators, Parasites and Diseases The Giant Eagle-owl *Bubo lacteus* preys on hedgehogs (Smithers 1968); when feeding, it peels and discards the spines from the body (Kemp & Calburn 1987). Some humans catch hedgehogs for food.

Conservation IUCN Category: Least Concern.

Originally listed as a threatened species but now thought to be less threatened. In South Africa, considered as 'rare' (Smithers 1986) and protected by local ordinances. Numbers have probably declined because of changing land-use and increased use of pesticides (which kill prey species).

Atelerix sclateri **SOMALI HEDGEHOG**

Fr. Hérisson de Somalie; Ger. Somalischer Igel

Atelerix sclateri Anderson, 1895. Proc. Zool. Soc. Lond. 1895: 415. Taf, central Somalia.

Taxonomy The least well-known of African hedgehogs. Originally described in the genus *Erinaceus*, then moved to *Aethechinus*, but now considered to belong to *Atelerix* and closely related to *A. albiventris*. In N Somalia, populations of *A. sclateri* occur within about 100 km of populations of *A. albiventris* (Corbet 1988) without intergradation, and without any physical boundaries separating them. Possibly *sclateri* is a subspecies of *A. albiventris* (Corbet 1988). Synonyms: none. Chromosome number: not known.

Description Large hedgehog with five digits on hindfoot. Dorsal pelage of dark spines. Surface of spines smooth and without papillae. Ventral pelage of non-spiny hairs; hairs white or buffy-white with dark patches posteriorly. Spiny dorsal pelage and hairy ventral pelage clearly delineated on lower flanks. Head with white forehead from cheek to cheek; narrow central parting of spines on crown of head; black face-mask with slight posterior extension of black colouration on cheek. Ears small, rounded, shorter than adjacent spines; ca. 88% of HF. Limbs short, dark; forefeet with five digits; hindfeet with five digits, Digit 1 small. Tail very short with small pale hairs, barely visible. Nipples: not known. Glans penis – no information. Skull: auditory bullae comparatively small; P³ with two roots, barely divergent. See Table 6.

Geographic Variation None recorded.

Similar Species

Atelerix albiventris. Four digits on HF; limbs pale; widespread in savanna habitats south of the Sahara and north of the Zambezi R. Allopatric.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from a few localities in N Somalia. Not recorded from neighbouring Djibouti (Pearch *et al.* 2001) or Ethiopia (Yalden *et al.* 1976).

Habitat Most specimens found on ‘maritime plain close to hills’ near Berbera. Altitude range: 10 m (near Berbera) to 1360 m (near Upper Sheik).

Abundance Uncertain; known from only a few specimens from about seven localities. Said to be ‘fairly common on the maritime plain’ (R. E. Drake-Brockman; label, BMNH).

Remarks Apparently no other information available. Presumed to be similar in many respects to other hedgehogs in arid habitats.

Atelerix sclateri

Conservation IUCN Category: Least Concern.

The few known specimens, small distribution and absence in locations where it would be expected to occur suggest that the species is threatened and should be classified as Vulnerable.

D. C. D. Happold

GENUS *Hemiechinus*

Long-eared Hedgehog

Hemiechinus Fitzinger, 1866. Sitzb. Akad. Wiss. Wien 54, 1: 565. Type species:
Erinaceus platyotis Sundevall, 1842 (= *Erinaceus auritus* Gmelin, 1770).

Figure 7. Skull and mandible of *Hemiechinus frontalis* (BMNH 92.7.1.2).

The genus contains four species widely distributed in the temperate and semi-desert regions from NE Africa and the Middle East to central China and NW India. Species in the genus are distinguished by the absence of a parting of the spines on the crown of the head, papillate spines with grooves, very large ears, narrow palatal shelf and enlarged auditory bullae (Figures 4 and 7). Digit 1 of the hindfoot

is well developed. Hutterer (2005a) includes *Paraechinus* within this genus, but following Corbet (1988), *Paraechinus* is retained as a valid genus here. The single species in Africa, *Hemiechinus auritus*, occurs only in the extreme NE of the continent.

D. C. D. Happold

Hemiechinus auritus LONG-EARED HEDGEHOG

Fr. Hérisson à grandes oreilles; Ger. Langohr-Igel (Grossohrige)

Hemiechinus auritus (Gmelin, 1770). Nova Comm. Acad. Sci. Petropoli 14: 519. Astrakhan, S. Russia.

Taxonomy Originally described in the genus *Erinaceus*. A central Asian and Middle Eastern species, which has its extreme western boundary in coastal Egypt and Libya. Many synonyms (extralimital to Africa; see Corbet 1988, Hutterer, 1993, 2005a). Synonyms: many (mostly extralimital to Africa – see Hutterer 2005a). Subspecies: two (Egypt only). Chromosome number: $2n = 48$, $aFN = 92$ (Hübner *et al.* 1991).

Description Small pale hedgehog with five digits on hindfoot. Dorsal pelage of dark spines; spines banded, whitish at base, with two wide black bands separated by white band, and white tip. Surface of spines rough with numerous papillae and with many shallow longitudinal grooves. Ventral pelage of non-spiny soft white hairs. Spiny dorsal pelage and hairy ventral pelage clearly delineated on lower flanks. Head white without dark face-mask; no central parting of spines on crown of head (cf. all other African hedgehogs). Ears large, slightly pointed, flexible and mobile, considerably longer than adjacent spines; ca. 114% of HF. Limbs rather long for a hedgehog, white; forefoot with five digits; hindfoot with five digits. Tail relatively very short and barely visible (ca. 15% of HB) with small pale hairs. Nipples: usually 5 pairs. Glans penis with two tracts of spines on upper surface; not expanded laterally. Skull: auditory bullae enlarged, but smaller than in *Paraechinus aethiopicus* (see Measurements); P^3 with 1–3 roots. See Table 6.

Geographic Variation Considerable variation throughout range. In Egypt, Osborn & Helmy (1980) recognize two subspecies:

- H. a. aegyptius*: Nile Delta and Sinai. Darker colouration, tail longer.
- H. a. libycus*: coastal desert regions west of the Nile Delta. Paler colouration, tail shorter.

Similar Species

- Paraechinus aethiopicus*. Wide central parting on crown; black face-mask; Sahara and northern semi-arid regions.
- Atelerix algirus*. Narrow central parting on crown; spines smooth; ears shorter than adjacent spines; Morocco to Tunisia only.

Distribution North-eastern part of Sahara Arid BZ. Recorded from coastal Egypt and Libya. Extraliminally throughout Middle East, central Asia north of the Himalayan Mts to Mongolia and China (see Corbet 1988).

Habitat Coastal semi-desert and scrub with dense vegetation. Prefers mesic habitats such as gardens, olive groves and cultivated areas.

Abundance Not uncommon in suitable habitats.

*Hemiechinus auritus*

Adaptations Nocturnal and terrestrial. Although the Long-eared Hedgehog lives in semi-arid countries, it is not desert-adapted as is the Ethiopian Hedgehog *Paraechinus aethiopicus*. Nevertheless, it is moderately tolerant of heat and drought, and the large ears may be used for thermoregulation (Hufnagl 1972). During the day animals rest in burrows 20–90 cm long, which they dig themselves or in burrows originally made by rodents; at other times they rest in caves and crevices and under piles of rocks and bricks. Their long limbs enable them to walk and run quickly.

Comparative studies show that metabolic rate is 64% of that predicted on the basis of weight (cf. European Hedgehog *Erinaceus europaeus*: 98%). Evaporative water loss is similar to that of the European Hedgehog at low T_a , but lower at high T_a ; for example, at $T_a = 30^\circ\text{C}$ water loss is 1.0 ml/g/h and at $T_a = 40^\circ\text{C}$ water loss is 4.0–8.2 ml/g/h (see also *Paraechinus aethiopicus*) (Shkolnik 1980). In this respect, Long-eared Hedgehogs fall midway between the temperate *Erinaceus europaeus* and the desert-adapted *Paraechinus aethiopicus*. During the cold season in North Africa (ca. Dec–Feb) they may go into torpor and remain in their burrows for periods of 5–40 days (Schoenfeld & Yom-Tov 1985).

Studies in Israel (where the climate is similar to that of North Africa) have revealed other aspects of the biology of the species (Schoenfeld & Yom-Tov 1985). During the course of a year, hedgehogs undergo regular fluctuations in weight. Mean maximum weight of 280 g is in summer (when food is abundant); weight declines in autumn to 260 g and to the minimum of 235 g during winter. Loss of weight is associated with torpor when hedgehogs utilize their fat reserves. In an area of ca. 500 ha, mean home-ranges were 4.9 ha for ♂♂ and 2.8 ha for ♀♀. Home-ranges for lactating

♀♀ were larger (mean = 3.5 ha) than for non-lactating ♀♀ (mean = 1.3 ha). Radio-tracking showed that individuals sometimes walk 1000 m during the course of night.

Foraging and Food Primarily insectivorous. In Israel, the diet (of this species and *Erinaceus europaeus*) included many insects (bugs, beetles, grasshoppers and ants), millipedes and snails. During spring, snails were a favoured food (Schoenfeld & Yom-Tov 1985).

Social and Reproductive Behaviour No information for Africa. Courtship behaviour is well developed, and includes sniffing, licking of the genitalia and flank-rubbing (Poduschka & Poduschka 1986, in Reeve 1994).

Reproduction and Population Structure In Egypt, litters of one and two young were recorded in May, and five in Aug (Flower 1932). Births were recorded in Jun (Israel; Schoenfeld & Yom-Tov 1985), and in Jun or Jul–Oct, with a peak in Aug (India; Prakash 1966 in Nader 1968). Litter-size: 2.5 (1–6) (Prakash 1960). Typically eyes open ca. Day 16, solid food eaten Day 21–28, and young are weaned at ca. Day 40 (Poduschka & Poduschka 1986).

Predators, Parasites and Diseases In Israel, ectoparasites include one species of tick *Rhipicephalus sanguineus* and one species of flea *Archaeopsylla erinacei* (Schoenfeld & Yom-Tov 1985). In Egypt, 11 species of fleas in seven genera have been recorded; many of these are widespread species, which also parasitize other mammalian species (Lewis 1967).

Conservation IUCN Category: Least Concern.

A widespread species and unlikely to be threatened.

GENUS *Paraechinus*

Desert Hedgehog

Paraechinus Troussart, 1879. Rev. et Mag. de Zool. 3 (7): 242. Type species: *Erinaceus micropus* Blyth.

Contains three species of 'desert hedgehogs', which live in arid habitats of North Africa and the Middle East. The genus is distinguished by the wide central parting of spines on crown of head, papillate spines with grooves, large ears, broad palatal shelf and especially enlarged auditory bullae (Figures 4 and 8). Digit 1 of hindfoot is well developed (cf. *Atelerix* spp.). Members of the genus are better adapted to arid conditions than other hedgehogs. *Paraechinus* is considered to be a subgenus of *Hemiechinus* by Hutterer (1993, 2005a), although retained as a valid genus by Corbet (1988). The single African species occurs only in the arid and semi-arid regions in and around the Sahara Desert.

D. C. D. Happold

Figure 8. Skull and mandible of *Paraechinus aethiopicus* (BMNH 66.5581).

Paraechinus aethiopicus DESERT HEDGEHOG (ETHIOPIAN HEDGEHOG)

Fr. Hérisson du désert; Ger. Wüstenigel

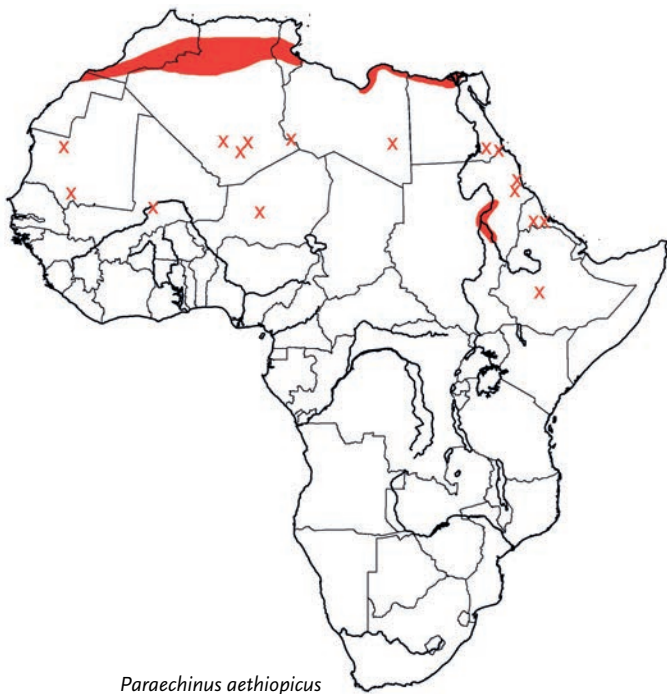

Paraechinus aethiopicus (Ehrenberg, 1832). Symb. Phys. Mamm. 2; footnote. Dongola desert, Sudan.

Taxonomy Originally described in the genus *Erinaceus*. The widespread distribution, and the large amount of individual variation, has resulted in many names, at species and subspecies level, being applied to this species. Osborn & Helmy (1980) regard *aethiopicus*, *dorsalis* and *deserti*, all of which occur in Egypt, as full species, a view not supported by Corbet (1988) and Hutterer (1993, 2005a). Here, placed in the genus *Paraechinus* (following Corbet 1988), not in the genus *Hemiechinus* as given by Hutterer (2005a). See also genus profile. Synonyms: *albatus*, *albior*, *blancalis*, *brachydactylus*, *deserti*, *dorsalis*, *ludlowi*, *oniscus*, *pallidus*, *pectoralis*, *senaariensis*, *wassifi*. Subspecies: none recognized here. Chromosome number: $2n = 48$, $FN = 90$ (Saudi Arabia; Harrison & Bates 1991).

Description Medium-sized hedgehog with five digits on hindfoot (as in *Hemiechinus*). Dorsal pelage of dark spines; spines banded, whitish at base, with two wide black bands separated by white band, and white tip. Surface of spines rough with numerous papillae and with many shallow longitudinal grooves. Ventral pelage of non-spiny hairs;

rather sparse; hairs mostly white but may be brown posteriorly or have brown patches on chest in some individuals. Spiny dorsal pelage and hairy ventral pelage clearly delineated on lower flanks. Head with broad white forehead from cheek to cheek; wide central parting of spines on crown of head; face-mask on muzzle and around eyes black, well defined, extending posteriorly on to the lower cheek (see also below). Ears large, slightly pointed, usually longer than adjacent spines; ca. 132% of HF. Limbs rather long for a hedgehog, dark brown; forefeet with five digits; hindfeet with five digits (Digit 1 may be slightly reduced). Tail relatively very short (<1% of HB), barely visible, with small pale hairs. Glans penis with two tracts of spines (sometimes each with two rows of spines) on upper surface. Skull: auditory bullae enlarged (more so than in other species of hedgehogs; see Measurements); P^3 with one root. Nipples: four pairs. See Table 6.

Geographic Variation There is considerable variation in the extent of the brown colouration of the ventral pelage in different parts of the range.

Similar Species

Atelerix albiventris. Narrow central parting on crown; spines smooth; four digits on HF; ears shorter than adjacent spines; widespread in savanna habitats south of the Sahara and north of the Zambezi R.

A. algirus. Narrow central parting on crown; spines smooth; no face-mask (some 'spotting' on muzzle); five digits on HF; ears shorter than adjacent spines; Morocco to Tunisia only.

Hemiechinus auritus. No central parting on crown; no face-mask; five digits on HF; ears very large, much longer than adjacent spines; Egypt and Libya only.

Distribution Sahara Arid BZ and in the semi-arid regions to the north and south of the desert. Widely distributed. Recorded from Mauritania and Morocco to Egypt, Sudan and N Ethiopia. Also Djerba I. (Tunisia). Populations are mostly scattered and isolated (as a result of increasing aridity in the area of distribution in recent millennia). Not recorded from coastal regions of Morocco, Algeria or Tunisia. Also occurs extralimittally in Saudi Arabia, Israel, Jordan, Iraq and the Gulf States (Harrison & Bates 1991).

Habitat Desert and dry scrub, often on stony plains, jebels and in mountainous desert country (e.g. Hoggar); also in more mesic regions such as near oases and vegetated wadis.

Abundance Generally uncommon, but may be common in selected localities. Populations are scattered and isolated, and do not occur throughout the whole geographic range. Not uncommon in (irrigated) gardens and fields in parts of the range (e.g. Libya; Hufnagl 1972).

Adaptations Little is known about this species in the wild (Corbet 1988). Desert Hedgehogs appear to be better adapted to arid conditions than the other species of African hedgehogs. Nocturnal and terrestrial. During the day, rest in crevices in cliffs, under clumps

of vegetation, or in burrows and, unlike other hedgehogs, may dig their own burrows (Herter 1968). During the winter (cool season) in the desert, when the night air is cold and food is less abundant, they enter torpor (and hence are rarely seen). In Algeria, hedgehogs are torpid during the months of Nov–Mar (Kowalski & Rzebik-Kowalska 1991); during these months they usually emerge every few days to feed (Harrison & Bates 1991).

Desert hedgehogs show two adaptations that are clearly associated with the desert habitat: low metabolic rate and low evaporative water loss. In captive animals, metabolic rate (as measured by oxygen consumption) is only 51% of what is predicted on the basis of weight (cf. European Hedgehog: 98%). Evaporative water loss is comparatively lower than that of the European Hedgehog; for example, in the Desert Hedgehog at $T_a = 30^\circ\text{C}$ water loss is 0.55 ml/g/h; at $T_a = 40^\circ\text{C}$ water loss is 3.3–4.5 ml/g/h; equivalent figures for the European Hedgehog are 2.6 and 6.7–10 ml/g/h (Shkolnik 1980). T_b at normal T_a is around 34°C ; there is no information on the T_b of torpid Desert Hedgehogs.

Long limbs enable fast walking and trotting: one individual was followed at a steady 10 km/h for five minutes in Libya (Hufnagl 1972).

Foraging and Food Primarily insectivorous. In Algeria, the diet comprises insects, eggs, agamid lizards and snakes, and they are also reported to eat scorpions (Sellami *et al.* 1989, Kowalski & Rzebik-Kowalska 1991).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Litter-size: 2–5. Weight of young at birth: 8–9 g. Growth rate: 20 g at Day 10; 40 g at Day 20; 60 g at Day 30; 80 g at Day 40; 150 g at Day 60. Growth rate to 6 weeks: 1.7 g/day; from 6 to 9 weeks: 3.5 g/day. Eyes open: Day 21–22. Solid foods eaten: Day 44. Fully weaned: Day 58 (Eisentraut 1952, Reeve 1994). Growth to weaning is longer than in other species of hedgehogs. Thermoregulation fully developed at about Day 44 when solid food is first eaten. No information on number of litters/year, or on average longevity.

Predators, Parasites and Diseases In Algeria, hunted by jackals. Remains of young hedgehogs found in the pellets of owls (species unknown) (Kowalski & Rzebik-Kowalska 1991). Also eaten by humans in some parts of the range (e.g. in Algeria; Sellami *et al.* 1989). Two species of fleas recorded on Desert Hedgehogs in Egypt: *Synosternus pallidus* (common on several species of hedgehogs and carnivores) and *S. cleopatrae* (common on gerbils) (Lewis 1967).

Conservation IUCN Category: Least Concern.

Order SORICOMORPHA – Shrews, Moles, Shrew Moles, Desmans and Solenodons

Soricomorpha Gregory, 1910. Bull. Amer. Mus. Nat. Hist. 37: 465.

| | | |
|--|--------|-------|
| Soricidae (9 genera, 150 species) | Shrews | p. 43 |
|--|--------|-------|

The order Soricomorpha includes a multitude of shrew-like forms that feed primarily on invertebrates, including insects, other arthropods, molluscs and earthworms. They have elongated, flexible snouts, prominent vibrissae and numerous small pointed teeth. The external ears are small and rounded. The eyes are minute. The pelage is short and dense with a velvety touch. They are mostly terrestrial and ground-dwelling, and run with a plantigrade gait. They include some of the smallest of all living mammals, and range in size from the tiny shrews such as *Suncus etruscus* and *Sorex minutissimus* weighing 1.5–2 g, to the stoutly built solenodons such as *Solenodon paradoxus*, weighing up to 1 kg. Although soricomorphs resemble more closely the generalized, primitive mammalian condition than other Recent placental mammals, the earlier viewpoint that they were ancestral to the other eutherian (placental) orders of mammals and defined by primitive characters has largely been abandoned (Butler, 1988). Their geological range is early Eocene to Recent (Miocene to Recent in Africa).

Extant members of the Soricomorpha are distributed widely throughout Eurasia, North America, Africa and southern Asia. Only after the formation of the Pliocene land bridge did they reach South America, but only one genus, the shrew *Cryptotis*, has successfully colonized the Neotropics. They have never been present in Australia and are absent from the polar regions.

The soricomorphs (as currently understood) were previously assigned to the order Insectivora, along with many other small fossil and extant mammals with primitive characters such as hedgehogs

(Erinaceidae), golden-moles (Chrysochloridae), tenrecs (Tenrecidae) and elephant shrews or sengis (Macroscelidae). It was long argued that, because of the primitive features possessed by all these insectivorous mammals, they exhibit closer affiliations with the ancestral stock of mammals than do any other living groups. However, the composition of the group has never been fully agreed upon and the proposal that they represent a monophyletic group descended from a single common ancestor has been hotly debated. Cladistic analysis suggests that living insectivores are united by derived anatomical features (MacPhee & Novacek 1993). Molecular studies have cast further doubt on the phylogeny and affiliations of these insectivorous mammals and alternative groupings have been proposed (Springer *et al.* 1997, Stanhope *et al.* 1998, Madsen *et al.* 2001, Murphy *et al.* 2001a).

The taxonomy adopted by Wilson & Reeder (2005) is followed here: the order Insectivora is replaced by three orders, these being Afrosoricida (Tenrecidae, Chrysochloridae), Erinaceomorpha (Erinaceidae) and Soricomorpha (Soricidae [shrews], Talpidae [moles, shrew moles and desmans], Solenodontidae [solenodons] and the extinct Nesophontidae [West Indian shrews]). The Macroscelidae has, for many years, been placed in an order of its own, the Macroscelidea (Schlitter 1993, 2005). The Afrosoricida and Macroscelidae are now placed in the Afrotheria (see Volume I of *Mammals of Africa*). Within the Soricomorpha, only the Soricidae are found in Africa. In comparison with the wealth of information about the biology and ecology of shrews from temperate regions, African species are poorly documented.

The family Soricidae – the shrews – contains 23 Recent genera and some 374 species (Hutterer 2005b), and has many more representatives than any other family of insectivorous mammals. The Soricidae has radiated to fill the terrestrial insectivore niche in most habitats in both temperate and tropical regions. It has the widest distribution of any family of insectivorous mammals, being found in Eurasia, South-East Asia and the Americas, as well as in Africa. Shrews are by far the most numerous and widespread of the terrestrial insectivorous mammals found in Africa. The number of species of shrews in Africa is uncertain and is under constant review as more species are encountered, particularly

in little-known forested and montane areas, and as other previously described taxa are placed in synonymy. Wolsan & Hutterer (1998) record 149 species of shrews in Africa, and Hutterer (2005b) lists 148 species. Here, nine genera and 150 species are recognized (Tables 7 and 8). Within the Soricidae, three clades are recognized, supported by allozyme data and rRNA sequence data (Maddalena & Bronner 1992, Quérrouil *et al.* 2001). Hutterer (2005b) retains these clades at the subfamily level: Soricinae (red-toothed shrews), Crocidurinae (white-toothed shrews) and Myosoricinae. All African shrews are members of the Crocidurinae or Myosoricinae, and the most widespread genus is *Crociodura*, with ca. 105 species recognized at present. The taxonomy of *Crociodura* is complex and some species are morphologically so similar that they are assigned to ‘species groups’. Multivariate analyses of morphological characters to distinguish species is hampered by the lack of specimens available in many cases but recent genetic analyses are providing a means of differentiating morphologically similar species, and molecular approaches are giving further insights into species boundaries and phylogenetic relationships within African *Crociodura* species groups (e.g. Quérrouil *et al.* 2001, 2005). This profile from here on primarily pertains to the Soricidae of Africa. Detailed information on the natural history of shrews is given by Churchfield (1990).

Table 8. Shrews of Africa arranged by size (mean HB and then CI) within eight size categories.

Habitat: a = arid/semi-arid, s = savanna, f = rainforest, fs = rainforest + savanna, m = montane, com = commensal.

Regions: c = central Africa, e = eastern Africa, n = northern Africa, s = southern Africa, w = western Africa, ec = east-central Africa.

| Genus | Species | Mean HB (mm) | Mean CI (mm) | T % of HB (approx) | Habitat | Regions |

Shrews are typically small, fast-running, terrestrial or semi-fossorial insectivores with long pointed snouts, minute eyes, small ears, short limbs, long tails and short dense fur. The eyes are small, and most species have poor eyesight so prey are located largely by smell, touch and by random searching. African shrews range in size from the tiny *Suncus etruscus* and *S. infinitimus* of about 2.0 g to the large, rat-sized *Crocidura olivieri*, *C. goliath* and *Scutisorex somerani*, which have mean weights of ca. 60 g. The limbs are unspecialized, with five digits on each limb. Shrews have a generalized quadrupedal

locomotion and a plantigrade gait, running with the sole and heel of the foot touching the ground. Neither the thumb nor big toe is opposable, so items such as food cannot be grasped freely by the hand. The radius and ulna are separate but the tibia and fibula are fused near the ankle. Like all soricomorphs, shrews possess clavicles. Members of the Soricidae have primitive brains and depend more on olfaction than on vision: the olfactory bulbs are very large but the eyes and optic foramina are small, and visual acuity is poor. Unlike most other eutherian mammals, the cerebral hemispheres are

smooth and with little convolution, and they usually do not extend backwards to cover the cerebellum or corpora quadrigemina. The neopallium and corpus callosum are very small. In outline, the skull is low and flat, and often long and slender. The braincase is small, the orbits open laterally, auditory bullae are absent, and zygomatic arches are absent or much reduced.

The first set of teeth of shrews is deciduous and is shed before birth. All the teeth are rooted. Unlike rodents, the incisors do not grow throughout life and they wear down as the animal ages. In the soricine shrews, the tips of the teeth are reddish in colour resulting from the deposition of iron in the outer enamel, a condition that is thought to increase resistance to wear. The total number of teeth in extant species of shrews varies between 28 and 32. Shrews normally have six teeth on each side of the lower jaw but a variable number in the upper jaw. The anterior dentition is specialized by the enlargement of the first upper incisor, which is large and hooked, and bears a notch and a cusp. The first lower incisor is also enlarged and is procumbent. Together these teeth function as fine forceps for grasping small invertebrates. The first upper incisor is followed by several small, unicuspid teeth (I^2 , I^3 , C, P^1 , P^2 , P^3), all rather similar in form; the number varies according to the genus, but in some genera there are only three unicuspid teeth (I^2 , I^3 , C; also referred to as U^1 , U^2 and U^3). The remaining premolars and molars (P^4 , M^1 , M^2 and M^3) are large and possess sharp, high-pointed cusps, which can crush the tough, chitinous exoskeletons of invertebrate prey (Figure 9).

The genital and urinary systems of shrews have a common exit through a cloaca. The sexes are difficult to distinguish externally, particularly in immature individuals. The penis is usually retracted into the abdomen when not in use and, in immature $\sigma \sigma$, is small and poorly developed. The testes are abdominal and do not descend into a scrotal sac, even when the $\sigma \sigma$ are mature. However, breeding $\sigma \sigma$ can be distinguished by the swollen testes on either side of the anus. In breeding ♀ the nipples are easily seen. In immature ♀ of many species, a small dark patch of fur marks the position of each nipple.

Shrews can be found in most terrestrial habitats, including forest, scrub and grassland, and at a wide range of altitudes. Some are fossorial (e.g. *Scutisorex*) and some (e.g. *Ruwenzorisorex*) are semi-aquatic. Shrews are most abundant in moist, well-vegetated habitats but a few are well adapted for life in xeric habitats. Some inhabit montane areas, for example *Crociodura montis* occurs in the afroalpine zone on Mt Elgon, Uganda at altitudes of 3300–4200 m. Many are commonly found in man-made habitats, especially in plantations and cultivated areas. Several are commensal with humans, and frequent gardens, shambas, houses and outbuildings, e.g. *Crociodura russula*, *C. olivieri* and *Suncus murinus*.

Many are proficient burrowers, and most can climb and swim well. The small size of shrews permits them to exploit a variety of habitats and penetrate narrow spaces, cracks and crevices in search of food and suitable nest sites. Many may utilize the tunnels of other small mammals for shelter and foraging. They frequent dense vegetation and find shelter

under logs, among rocks, beneath the roots of trees and under piles of dry brush and grass, and hence are rarely seen. Even the larger forms can remain unseen in dense forest with thick undergrowth.

Shrews feed on a variety of invertebrates. The principal prey of most species is arthropods (primarily insects), molluscs and earthworms. But they are highly opportunistic and larger species will also prey upon fish, amphibians and small reptiles. They may augment the diet with carrion and many consume some plant material, particularly seeds. No African shrews have been found to possess venomous saliva. Shrews have a reputation for voracious appetites and little resistance to starvation, needing to feed frequently day and night in order to survive. They have average daily energy expenditures significantly greater than those of rodents of similar size, and their basal metabolic rates are well above those predicted on the basis of size and weight. Soricine shrews have particularly high metabolic rates and energy requirements. Crocidurine shrews have lower metabolic rates and smaller food requirements. *Sorex araneus* (a non-African species) of about 9 g body mass requires 90% of its body weight in food or 9.7 kJ/g/day whereas *Crocidura russula* of similar size requires only 48% of its body weight or 3.4 kJ/g/day (Genoud 1985, Churchfield 1990). The large food requirements of these mammals are attributed to the high water content and indigestible chitin content of prey, as well as high metabolic rate. With their high metabolic rates, small body size and inability to store large quantities of fat as a food reserve, shrews are incapable of hibernating or entering extended torpor during critical periods of stress due to cold, heat, drought or food shortage. However, many crocidurine shrews exhibit short, daily periods of torpor with hypothermia. The African species *C. russula* can be induced to enter daily torpor by decreasing the availability of its food, during which the metabolic rate and body temperature are reduced (Genoud 1985).

It is common for several species of shrew to be syntopic as well as sympatric. It is not unusual for five or more species to coexist in the same habitat. In the forests of West and central Africa between eight and 16 syntopic species of shrews have been found (Dieterlen & Heim de Balsac 1979, Ray & Hutterer 1995, Churchfield *et al.* 2004, Dudu *et al.* 2005). In multi-species communities of shrews there is evidence of resource partitioning on the basis of body size: very small species are primarily epigeal foragers on small invertebrates active on the ground surface whereas large species are hypogeal foragers, subsisting mostly on larger, soil-dwelling prey (Churchfield *et al.* 1999, Dudu *et al.* 2005).

Shrews generally have poor vision, and they rely on tactile, auditory and olfactory senses for navigation and orientation around their home-ranges, for locating prey and for intra-specific communication. The sense of touch is well developed. The long flexible snout so characteristic of these mammals is well furnished with touch-sensitive vibrissae whose follicles are well supplied with nerve endings and which are useful in orientation and location of prey. Hearing is keen and shrews are able to produce and perceive a wide range of sounds, from squeaks and shrieks to grunts and snuffles, both in the audible range of human hearing and at ultrasonic frequencies. Shrews are highly vocal, particularly during social interactions and agonistic behaviour (Gould 1969). They emit high-pitched twitters as they explore and forage, and during interactions between the ♀♀ and her young. Young shrews produce staccato 'barks' to attract the mother's attention. Loud

squeaks and rolling 'churls' are used by shrews when threatened or alarmed, and in aggressive meetings between individuals. Scent forms an important means of intra-specific communication, being used to indicate gender and reproductive condition and to delineate territories. Shrews have lateral flank glands situated mid-way between the fore- and hindlimbs. These are small, well-vascularized oval areas, which are present in both sexes but which are best developed in sexually mature ♂♂. They exude a greasy secretion that rubs off on vegetation as they pass by. Shrews frequently defecate in prominent places, suggesting another means of scent-marking. The musk shrews, *Crocidura* spp., are particularly odoriferous, exuding a sweet, musky scent. Females, and especially ♂♂, of *C. flavescens* actively scent-mark by rubbing the lateral glands against objects (Baxter & Meester 1982). Crocidurine shrews also possess anal or caudal glands at the base of the tail, and chin/neck glands, that are used for scent-marking. In *C. flavescens* scent-marking is very evident after aggressive encounters.

Most shrews are solitary and intolerant of conspecifics. There is evidence of territoriality in crocidurine and soricine shrews. They generally occupy individual territories that are largely mutually exclusive, although during the breeding season the territory or home-range of the ♂ is extended to overlap those of several ♀♀ (Churchfield 1990). Meetings between conspecifics, when they occur, are aggressive affairs: shrews squeak loudly, bite and wrestle with each other. Some species are more social: crocidurine shrews such as *C. hirta* and *C. russula* are aggressive towards strangers but will share nests with familiars (Meester 1963, Cantoni & Vogel 1989). Territoriality and sociability may vary seasonally. In winter, the home-ranges of individuals of *C. russula* overlap extensively, but there is strict territoriality between ♂♂ and between ♀♀ in summer and the formation of monogamous breeding pairs, which share nests (Cantoni & Vogel 1989). Home-ranges or territories range greatly in size between species, e.g. 75–395 m² in *Crocidura russula* and 400–2800 m² in (non-African) *Sorex araneus* (Genoud 1978, Churchfield 1990).

Many crocidurine and mysoricine shrews are capable of breeding whenever conditions are favourable, but most African species breed mostly during warm, wet months and reproduction declines in the dry season (Dieterlen & Heim de Balsac 1979, Rowe-Rowe & Meester 1985b). The breeding season of *Myosorex* shrews in southern Africa coincides with the onset of the rains but is also influenced by temperature; those at higher altitudes commence breeding later than those at lower altitudes (Rowe-Rowe & Meester 1985b, Baxter 2005). Shrews normally produce 2–3 litters during a breeding season. They have a postpartum oestrus allowing litters to be produced in quick succession when conditions are favourable. Gestation varies from about 24 to 33 days, according to species. Litter-size is generally large but it varies between species; crocidurine shrews have smaller litter-sizes (usually 3–4 young/litter) than soricines (5–7 young/litter). Young shrews are born naked and hairless but growth is rapid and within a few days the pelage is evident. In *Crocidura* and *Myosorex*, the eyes are open between Day 12 and 18 and they take their first invertebrate prey at around Day 19. Weaning occurs at about three weeks of age. Caravanning behaviour has been observed in some species, notably crocidurine shrews such as *C. bicolor*, *C. russula* and *Suncus etruscus*; when the young first leave the nest, the mother leads them along in a line, each young grasping the base of the tail of the

one in front (Ansell 1964, Fons 1974, Churchfield 1990). In tropical species there is rapid growth to sexual maturity, e.g. crocidurine shrews can mature and commence breeding within a couple of months of birth. Paternal care is rare amongst shrews, and the presence of the ♂ is usually not tolerated by the ♀. However, in some crocidurine shrews (e.g. *C. russula* and *Suncus varilla*) monogamous breeding pairs are formed, and the ♂ stays in attendance and may help to shelter the young (Cantoni & Vogel 1989, Lynch 1990, 1991).

Shrews undergo seasonal cycles in abundance. These are particularly well-documented in species in temperate regions where many mark–recapture studies have been carried out. Numbers are high in the temperate summer when breeding occurs but decline through autumn and into winter as young disperse and old adults die after breeding is completed. Similar trends in population dynamics have been found in *Myosorex* spp. in southern Africa (Rowe-Rowe & Meester 1985b). In contrast, there is little information about population dynamics of African shrews in the tropics. Population densities vary greatly according to species and habitat and to the alternation of dry and wet seasons. Population densities of African shrews appear to be much lower than those of temperate species. For example, reported densities of *Suncus varilla* in southern Africa are 0.25–8.0/ha (Lynch 1990, 1991) while those of *Crocidura suaveolens* and *Sorex araneus* in Europe vary from 12–100/ha (Genoud 1978, Churchfield 1990).

Longevity varies largely according to size. Shrews are amongst the shortest-lived mammals. Life-span of wild-living *Myosorex varius* in southern Africa is about 12–17 months (Rowe-Rowe & Meester 1985b), very similar to that of soricine shrews (Churchfield *et al.* 1995). *Suncus varilla* can survive for 24–30 months (Lynch 1990, 1991). Although small crocidurine shrews such as *Crocidura russula* can live up to 4 years in captivity, few survive longer than 1.5 years in the wild (Vogel 1972, Jeanmaire-Besançon 1986). Mortality is highest in young animals as they disperse after weaning. Some 30–50% of soricine shrews die or disperse during the first two months of life and only 20–40% of the original cohort survive to breed (Churchfield *et al.* 1995).

The fossil record of shrews in Africa is fragmentary. The earliest known fossils (*Latetium* sp.) are from the mid-Miocene of Morocco (ca. 14 mya) and from the late-Miocene of Tunisia (ca. 12 mya) (Butler 1998). More recent fossils, from the Pliocene (ca. 2.5–3 mya) and Pleistocene (ca. 0.5 mya) are more widespread in distribution and have been found in NW Africa (Morocco, Algeria and Tunisia), East Africa (Omo and Hadar in Ethiopia, Kobi Fora, Rusinga and Isenya in Kenya, Olduvai and Laetoli in Tanzania), and in Zimbabwe and South Africa. Fossil shrews have not been found in the Sahara, West and central Africa. The fossil record suggests that shrews probably entered Africa from south-west Asia in the early Miocene when a land bridge connected south-west Asia with Arabia (and hence Africa). Additionally, and at a later date, some shrews entered North-West Africa from the western Mediterranean. *Myosorex* and *Sylvisorex* are known from the middle–late Miocene.

Crocidura (now the most speciose of the genera of African shrews) seems to have originated in Africa, although it is now widespread in Eurasia. Radiation of this genus seems to have started in Africa at the end of the Miocene (Butler 1998). The origins of other genera are less well known. Both morphological and molecular investigations indicate rapid radiation of *Crocidura* in Africa (Butler 1998, Quéroutil *et al.* 2005) with rapid morphological divergence occurring in

response to palaeo-environmental changes. The expansion of forested habitats during warm moist periods and their contraction in cool dry periods, during the Pleistocene and Holocene promoted the speciation of shrews, especially *Crocidura* spp., and allowed some to adapt to arid and semi-desert environments. In localities where the fossil record is good, several species may be distinguished; e.g. Butler & Greenwood (1979) recognized nine species from mandibular fragments (*Sylvisorex*, *Suncus* and *Crocidura* spp.) at Olduvai in Tanzania – a rich community similar to communities of shrews in some forested habitats today. Good reviews of fossil shrews are given by Heim de Balsac & Lamotte (1956, 1957) and Butler (1998) (and references therein).

Recent molecular findings (with rRNA sequencing) support evidence from external, cranial and dental characters that, amongst the genera of African shrews, two major lineages have emerged (Meester 1953, Heim de Balsac & Lamotte 1956, 1957, Quéroutil *et al.* 2001). The first includes *Myosorex* and *Congosorex* (supporting the existence of a myosoricine taxon) and the second includes the six remaining genera (*Crocidura*, *Paracrocidura*, *Ruwenzorisorex*, *Scutisorex*, *Suncus* and *Sylvisorex*). Although *Sylvisorex* appears to be polyphyletic, *Crocidura* is monophyletic and all species investigated, with representatives from India and Europe as well as Africa, seem to be closely related (Quéroutil *et al.* 2001). Grouping patterns of species from different continents suggest that there have been multiple exchanges between Africa and Eurasia (Quéroutil *et al.* 2001).

The genera, and species within each genus, are arranged alphabetically. In the Descriptions, an indication of the size of each species is recorded comparatively to other species in the family. The size categories (see also Table 8) based on head and body length (HB), are:

minute: less than 49 mm; very small: 50–59 mm; small: 60–69 mm; small–medium: 70–79 mm; medium: 80–89 mm; large: 90–99 mm; very large: 100–149 mm; extremely large: more than 150 mm.

The size categories of tail length as a percentage of head and body (see also Table 8) are: short: <40%; medium: 41–60%; long: 61–80%; very long: 81–100%; extremely long >101%.

Figure 10. Head and right forefoot of *Myosorex* (upper left), *Congosorex* (upper right) and *Surdisorex* (bottom) to show variation in shape of head, size of eye, shape of forefoot and length of claws (after Hutterer *et al.* 2001).

Shrews are not easy to identify. The most important characteristics are size and mass (Table 8), pilosity of the tail (Figure 11), and the fine details of the skull and teeth. Within Africa, the geographical distribution and habitat may help to narrow the number of possibilities for a correct identification. Because of the large numbers of species of shrews in Africa, and because the geographic distributions of many species overlap, it is not possible to provide full details of similar species in the species profiles. For *Crocidura*, the section on ‘Similar Species’ is omitted and for the other genera, ‘Similar Species’ is restricted to other species in the genus (see also Tables 7 and 8 for comparisons between genera and species).

Figure 11. Pilosity of the tails of shrews: 0% (left), 50% (centre), 100% (right).

GENUS *Congosorex* Congo Shrews

Congosorex Heim de Balsac and Lamotte, 1956. Mammalia 20: 167. Type species: *Myosorex polli* Heim de Balsac and Lamotte, 1956.

Congosorex polli.

The genus contains three species: two (*C. polli*, *C. verheyeni*) live in primary and secondary lowland rainforest, gallery forest and small savanna patches within the forest of the Congo Basin, and the third species (*C. phillipsorum*) lives in isolated montane forest, bamboo, or marshy habitats in the Eastern Arc Mts of SW Tanzania above 1500 m.

Congosorex was described as a subgenus of *Myosorex* (Heim de Balsac & Lamotte 1956), and treated as a full genus by Heim de Balsac (1967) and subsequent authors (Hutterer 1993, 2005b, Stanley *et al.* 2005a). The original description compared *Congosorex* with *Myosorex* (*sensu stricto*) and *Surdisorex*. The full variability and species composition of the genus is not yet known.

The characters of *Congosorex* are somewhat cryptic. Species of the genus resemble species of *Myosorex* externally, but limbs and tail in *Congosorex* are generally shorter (tail length 30–58% of HB, cf. 42–84% in *Myosorex*). Other characteristics of the genus are short dense pelage (long and dense in *Myosorex* and *Surdisorex*), large head relative to rest of body, moderate or large-sized ears (normal or reduced in *Myosorex*, atrophied in *Surdisorex*), moderate-sized forefeet and claws (large in *Myosorex*, very large in *Surdisorex*) (Heim de Balsac & Lamotte 1956), prominent scales on fore- and hindfeet, absence of long hairs on the tail (as in *Myosorex* and *Surdisorex*) and minute eyes (Hutterer *et al.* 2001). On the skull, braincase is wide and rostrum is short (giving a broader-looking skull than in other genera of African shrews), there are three upper unicuspid, fourth upper unicuspid

Figure 12. Skull and mandible of *Congosorex verheyeni* (ZFMK 99.932 [holotype]).

(P³) is absent (present in *Myosorex*, absent in *Surdisorex*) and M³ is large. Dental formula: I ³/₂, C ¹/₀, P ¹/₁, M ³/₃ = 28 (Figure 12). The tip of the phallus of male *Congosorex* is pointed, in contrast to the rounded condition found in *Myosorex* (Stanley *et al.* 2005a). Two vascular foramina are present between the parietal bones of the cranium, as in *Myosorex* and *Surdisorex* (see also Table 7).

The biology of any of the species is hardly known. Most specimens were collected in primary rainforest and, less frequently,

in secondary rainforest. The reduction of the limbs, tail and ear may indicate that foraging occurs in leaf litter or under logs, mosses or other cover.

Genetic data show that *Congosorex* is a sister taxon of *Myosorex*, and that both are members of the subfamily Myosoricinae (or tribe Myosoricini), which comprises *Myosorex*, *Congosorex* and probably

Surdosorex, and is the most ancient taxon of all living African shrews (Quérrouil *et al.* 2001, Hutterer *et al.* 2002).

The species are distinguished by tail and hindfoot length, and distribution.

Rainer Hutterer & William T. Stanley

Congosorex phillipsorum PHILLIPS'S CONGO SHREW

Fr. Musaraigne de Phillips; Ger. Phillips Kongo-Spitzmaus

Congosorex phillipsorum Stanley, Rogers and Hutterer 2005. J. Zool., Lond. 265: 271. Ndundulu Forest, Udzungwa Mountains, Tanzania.

Taxonomy A member of the Myosoricini with some characters shared with *Myosorex*. Synonyms: none. Chromosome number: not known.

Description Small-medium robust shrew with dark brown pelage and relatively large head. Dorsal pelage dark brown; hairs slate-grey, dark brown at tip. Hairs 5 mm (dorsal), 3 mm (ventral). Ventral pelage only slightly paler than dorsal pelage; hairs brown at tip. Head large relative to body (measuring about one-third of HB length). Vibrissae long (10–14 mm), thin, translucent. Ears barely visible, covered with long hairs. Fore- and hindfeet covered in dark conspicuous scales. Tail relatively medium long (55–60% of HB), only slightly bicoloured. Male phallus pointed. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Congosorex polli. Smaller (HB: 60 mm, n = 1), tail shorter (T: 24 mm, n = 1). DR Congo.

Congosorex verheyeni. On average smaller (HB: 59 [53–95] mm; tail shorter T: 20 [19–26] mm). Congo and Central African Republic.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Tanzania. Known only from the Ndundulu and Nyumbanitu forests of the Udzungwa Mts, Tanzania.

Habitat Undisturbed or slightly disturbed montane forests above 1500 m in Ndundulu and Nyumbanitu forests of the Udzungwa Mts where soil is moist; occasionally found in bamboo forests and marshy habitats (Stanley *et al.* 2005a). Known altitudinal range 1500–2086 m.

Abundance In one survey in Ndundulu Forest, Udzungwa Mts, comprised 53% of all shrews (4 spp., including *Myosorex kishaulei*, *Crocridura hildegardae* and *C. monax*).

Remarks Terrestrial and predominantly nocturnal. A sample of nine individuals (collected in July 2003) consisted of six ♂♂ and three ♀♀. The two ♀♀ examined were not pregnant. Testes length of four ♂♂ examined ranged from 5–7 mm (mean = 5.7); width 2.5–4 mm (mean = 3.4), with 50% of the sample exhibiting convoluted epididymes.

Conservation IUCN Category: Critically Endangered.

Threatened because of fragmented distribution and decline in suitable habitat.

Congosorex polli GREATER CONGO SHREW

Fr. Musaraigne du Congo; Ger. Grosse Kongo-Spitzmaus

Congosorex polli (Heim de Balsac and Lamotte, 1956). Mammalia 20: 155.
Lubondai via Tshimbulu (06° 30' N, 22° 39' E), Kasai Province, DR Congo.

Taxonomy Originally described in the genus *Myosorex*. Type species of the genus *Congosorex* (as defined by Heim de Balsac & Lamotte 1956, Hutterer *et al.* 2002); a sister taxon of *Myosorex* (Quéroutil *et al.* 2001) and probably also of *Surdisorex*. Synonyms: none. Chromosome number: not known.

Description Small shrew. Dorsal and ventral pelage brown, body hairs short. Head large compared to the rest of the body. Ear reduced but larger than in *C. verheyeni*. Eyes small and hidden by pelage. Forefeet short with moderately developed digits and claws; scales large, covering the dorsal surface of the forefeet. Hindfoot also short with short claws and large scales. Tail relatively short (ca. 40% of HB), covered with short hairs over its entire length; no longer hairs present. Skull with a short rostrum, narrow maxillary, wide interorbit and a wide and inflated braincase. Nipples: not known. See also genus profile.

Geographic Variation None recorded.

Similar Species

Congosorex phillipsorum. Larger (HB: 68–76 mm). Tail longer (T: 35–40 mm). Udzungwa Mts, Tanzania.

Congosorex verheyeni. Skull perhaps shorter (CI: 17.8–19.1 mm). Congo and Central African Republic.

Distribution Endemic to Africa. Southern Rainforest–Savanna Mosaic. Known only from the type locality in Kasai Province, DR Congo.

Habitat Not recorded; probably gallery forest in the savanna.

Abundance No information; one of the rarest African shrews.

Remarks Like *Congosorex verheyeni*, *C. polli* has short limbs and reduced eyes and ears, which may indicate a secretive life under litter, logs or below ground.

Conservation IUCN Category: Data Deficient.
Known only by a single specimen collected in 1955.

Congosorex verheyeni LESSER CONGO SHREW

Fr. Musaraigne petite du Congo; Ger. Kleine Kongo-Spitzmaus

Congosorex verheyeni Hutterer, Barrière and Colyn 2001. Bull. Inst. Roy. Sci. Nat. Belgique, Biol. 71 (suppl.): 7–16.

Mbomo (00° 24' N, 14° 44' E), Parc National d'Odzala, Congo.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Very small, stout shrew with a very short tail. Dorsal and ventral pelage dark brown. Body hairs short: 5 mm (dorsum), 3 mm (ventrum). Head comparatively large, distance from tip of nose to back of ear about one-third of head and body length. Nose and lips flesh-coloured. Vibrissae sparse, longest 12 mm. Ear present, reduced in size and covered by hairs. Eye opening minute, hidden by pelage. Forefeet short with moderately developed digits and claws; large scales cover dorsal surface of forefoot. Hindfoot also short with short claws and large scales. Tail very short (ca. 32% of HB), with 11 short and weak caudal vertebrae; pale-coloured, covered with short, black hairs over entire length. Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

Congosorex phillipsorum. On average larger (HB: 71.3 [68–76] mm); tail longer (T: 35–40 mm). Udzungwa Mts, Tanzania.

Congosorex polli. Skull perhaps longer (CI: 20.3 mm, n = 1). DR Congo.

Distribution Endemic to Africa. Rainforest BZ (Gabon sub-region) and adjacent Rainforest–Savanna Mosaic. Known from three localities in Odzala National Park, Congo, and four localities in Ngotto forest, Central African Republic. All localities are on the right (northern) bank of the Congo R.

Habitat Primary and secondary lowland rainforest. One specimen was collected in adjacent savanna and a few others in newly regenerated forest patches (Barrière *et al.* 2000).

Abundance Only 53 specimens have been collected at the present time. Never a dominant species of the community of shrews but may be locally common. In Odzala N. P. comprised only 1% of shrews (n = 255) in primary forest, and 3% (n = 142) in disturbed forest (Barrière 1997). In Ngotto N. P., comprised 2% of shrews in Batouri (primary forest, n = 1350, 18 spp.); 4% in Bambio (secondary forest, n = 27, 7 spp.); 8% in Grima (secondary forest, n = 63, 10 spp.); and 9% in Massangai (secondary forest, n = 66, 8 spp.) (Barrière *et al.* 2000).

Remarks Short limbs, reduced eyes and ears may indicate adaptations to a secretive life under litter, logs or below ground. May feed preferentially on subterranean invertebrates such as earthworms. Embryo number: 2 (n = 1; Ngotto forest; wet season; P. Barrière, unpubl.).

Congosorex verheyeni

Conservation IUCN Category: Least Concern.

Occurs in two National Parks in Congo and in Central African Republic.

Patrick Barrière & Rainer Hutterer

GENUS *Crocidura*

Shrews (White-toothed Shrews)

Crocidura Wagler, 1832. Isis, p. 275. Type species: *Sorex leucodon* Herman, 1780.

Crocidura flavescens.

Skeleton of *Crocidura* sp.

The genus *Crocidura* contains more species than any other genus of African mammals (see below), and is found throughout the whole continent and in every biotic zone. Because of the widespread geographic range of the genus, one or more species of the genus is found in almost every habitat except in the driest of deserts.

The characters of the genus include rather small size and slender build. Head and body ranges (according to species) from very small (*C. bottegoides*; HB: ca. 50 mm, HF: 10 mm, WT: 3 g) to large (*C. olivieri*; HB: up to 140 mm, HF: ca. 23 mm, WT: 65 g). The largest species (*C. goliath*, *C. olivieri*) are equivalent in size to a medium-sized murid rodent. Pelage colour is usually undistinguished – drab brown or grey, often paler on the ventral pelage, and without any special markings or colours. The head is pointed (more so than in other genera of shrews), with a long muzzle, which projects anteriorly beyond the nasal bones of the skull and, in life, is constantly wiggled from side to side (see below, and order profile). The rhinarium is simple, divided into two by a vertical slit between the two nostrils. Eyes are small but visible, and ears are small and rounded (slightly more prominent than in *Myosorex*) with a complex arrangement of folds on the inner surface. The fore- and hindfeet are short and simple, without hairs on the outer side of the hindfeet; forefeet have five digits, hindfeet have five digits, all with small claws. The tail is usually thicker towards the base, tapering to the tip, and (in most species) covered with small bristles and scattered long (usually) pale hairs. These long hairs are almost unique to this genus of shrews (also present, to a lesser extent, in *Suncus* and *Paracrocidura*) and are useful for species identification. The proportion of the tail covered with these long hairs is expressed as the ‘pilosity’ of the tail (Fig. 27); pilosity is the percentage of tail, measured from the base, which supports these long hairs (e.g. 0% [no long hairs], 50% [basal half of tail]; 75% [basal three-quarters of tail] and 100% [all of tail]). In external characteristics (except for size), *Crocidura* shrews show great morphological similarity and hence are very difficult to distinguish. The skull is elongated and low, without zygomatic arches (as in all shrews), the teeth are white (not pigmented). Dental formula: $I^{3/1}$,

$C^{1/1}$, $P^{1/1}$, $M^{3/3}$ = 28. All teeth are cuspidate, a typical condition in shrews and other insectivores. I^1 is long and hooked with two denticulations (cusps), the anterior one being larger than the posterior one, and is followed posteriorly by three unicuspid teeth (U^1 , U^2 , U^3) – not four as in most other genera of shrews (see Table 7), which are morphologically I^2 , I^3 and C (Hutterer 2005c). The unicuspid teeth are small; they usually vary in size, the smallest being the most posterior. There is only one premolar; this is P^4 (P^1 , P^2 and P^3 are lost) and is usually the largest tooth in the molar row. The premolar is followed by three molars; M^1 and M^2 are similar in size to P^4 , and like P^4 have a complicated W-shaped pattern of cusps and ridges. M^3 is much smaller and variable in size, with a simple cusp. The widest point of the skull is across the braincase. The mandible is elongated with only six teeth in each ramus; I_1 does not have denticulations, the coronoid process is tall, vertical and rises well above the mandibular process, and the angular process is elongated and usually the most posterior part of the mandible (Figure 13). Some species of *Crocidura* shrews have a very strong pungent odour, produced by numerous secretory glands in the skin and tail. See Table 7 for comparisons with other genera of shrews.

The number of extant species in the genus is uncertain, and has varied according to the authority and the methods of study. Dollman (1915a, b, c, d, e, f, 1916) recorded 126 species (plus five indeterminate) in Africa, and Hutterer (2005b) recognized 171 species worldwide, of which 106 (62%) are African. Here, 105 species of *Crocidura* are recognized and described; many other previously described taxa are now regarded as synonyms. *Crocidura* is also the most speciose of the nine genera of African shrews, comprising 70% of the 150 of the currently recognized species of African shrews.

Crocidura shrews are terrestrial, although a few species are scansorial. None are fossorial (cf. *Surdisorex*) or semi-aquatic (cf. *Ruwenzorisorex*). Little is known about the ecology of *Crocidura* shrews in Africa. Like other shrews, all are insectivorous, consuming a high proportion of their body weight in a 24-hour period. Species that have been studied feed on a wide variety of insects and other invertebrates (Churchfield *et al.* 2004). It is evident that many species of *Crocidura* (together with species from other shrew genera) can live syntopically, implying that there must be important mechanisms for avoiding competition. Studies in Gabon have recorded five species of *Crocidura* (plus up to four other species belonging to different genera) in the same study area (Nicolas *et al.* 2003).

Figure 13. Skull and mandible of *Crocidura olivieri* (HC 579).

Crocidura shrews rely on their olfactory senses rather than visual senses for communication and foraging. They have scent glands on many parts of the body, which determine social relationships. The eyes of *Crocidura* shrews are small (size varying by species) and are thought to be of limited value other than providing a general impression of light intensity. Shrews make a variety of vocalizations (see e.g. *C. flavescens*, *C. hirta* and order profile), which indicate specific emotions. *Crocidura* shrews are mostly solitary, except during mating and care of the young; the best known of social behaviours is caravanning of the young in some species (e.g. *C. hirta*, *C. fuscomurina* and *C. russula* among African species). The small size of *Crocidura* shrews (and other shrews) means thermoregulation is an important aspect of metabolism; very little is known about these topics for African species, although it is well known that individuals of *Crocidura* shrews are often torpid if kept in cool conditions, particularly if food is unavailable.

The systematics of *Crocidura* is difficult because of the similarity between species. Dollman (1915a *et seq.*) divided the genus into 22 groups on the basis of size, pelage colour, length of hairs, relative size and width of the second and third unicuspid teeth, size of M^3 , and pilosity of the tail – characters that are still considered to be useful at the present time. Heim de Balsac (in a series of papers) divided the African *Crocidura* into four groups: *dolichura* group (Brosset *et al.* 1965), *smithii* group (Heim de Balsac 1966), *flavescens* group (Heim de Balsac & Barloy 1966) and *bicolor* (*fuscomurina*) group (Heim de Balsac 1958).

Butler *et al.* (1989) studied the mandibles (a structure often found in owl pellets) and, using principal component analysis, sorted them into six groups (but with many outliers). Hutterer & Happold (1983) divided the 21 *Crocidura* shrews of Nigeria into seven groups on the basis of size, length of tail and habitat (forest or savanna). Karyological and molecular studies have not assisted, to any great extent, with the systematics of shrews; the chromosome number is known for some species (see e.g. Schlitter *et al.* 1999), but since most species have not been studied in this respect, such methods are, at the present time, of limited value for identification.

The genus is considered to be monophyletic (Quérrouil *et al.* 2001). Within the African Soricidae as a whole, two lineages are apparent. One of these corresponds to the subfamily Crocidurinae, contains *Crocidura*, *Sylvisorex*, *Suncus*, *Scutisorex* and *Ruwenzorisorex* (and *Paracrocidura*) (see also family profile). The second lineage (subfamily Myosoricinae [see Hutterer 2005b]) contains *Congosorex* and *Myosorex*. (*Surdisorex* was not included in this study.) An alternative view by Butler *et al.* (1989) is that *Crocidura* is not a natural taxonomic unit, rather it is polyphyletic and includes several lineages. Studies on the chromosomes of *Crocidura* (Maddalena & Ruedi 1994), but with only a limited number of species, show that within the genus, three evolutionary trends are apparent. The first retains a karyotype close to the ancestral state and is represented by species throughout the worldwide geographic range (and includes the African *C. luna*, *C. cf. bottegi* and *C. bottegi*); the second exhibits an increase in both the number of chromosomes and the fundamental number (due to fission) and includes most of the African *Crocidura*; and the third shows a reduction of both the number of chromosomes

Crocidura maurisca.

and the fundamental number (due to Robertsonian fusions) and is typical of the Palaearctic–Oriental species. Thus the majority of African *Crocidura* form a single clade, strongly suggesting that there was rapid evolution of the genus within Africa (Butler *et al.* 1989, Quérouil *et al.* 2001, 2005).

The fossil record of the genus (and indeed all shrews) in Africa is limited (Butler 1978). Shrews are thought to have originated in Eurasia (see family profile) in the Oligocene. The radiation of *Crocidura* seems to have started at the end of the Miocene (Butler 1978, 1998) just after a period of major extinction when many ecological niches became vacant (Maglio 1978). There are fossil *Crocidura* from the late

Pliocene (ca. 2 mya) of South Africa, and from the early Pleistocene (ca. 1.5 mya) of Tanzania (Butler 1978, 1998). Alternation of wet and dry periods during the Pleistocene undoubtedly assisted the amazingly successful adaptive radiation of *Crocidura* shrews.

The species of the genus are very difficult to identify on gross morphological characteristics. The following characters are helpful: body dimensions and weight, pilosity and relative length of tail, shape of skull, shape of I¹, relative size and shape of unicuspid teeth and M³, habitat and distribution.

D. C. D. Happold

Crocidura Aleksandrisi CYRENAICA SHREW

Fr. Crocidure de Libye; Ger. Cyrenien-Spitzmaus

Crocidura Aleksandrisi Vesmanis, 1977. Bonn. Zool. Beitr. 28: 3. Cyrenaica, 5 km W Toca, Libya (32° 31' N, 20° 34' E).

Taxonomy Looks like a small form of the European *C. suaveolens*. This species was referred to as *C. russula* by Ranck (1968). Synonyms: none. Chromosome number: 2n = 40 (P. Benda pers. comm.).

Description Small shrew. Pelage soft and short (hairs ca. 2 mm). Dorsal pelage greyish-brown, with slight tinge of russet; hairs dark grey at base, brown at tip. Ventral pelage grey to brownish-grey; hairs dark grey at base, grey to pale brown at tip. Colour of head similar to dorsal pelage. Chin, throat and chest grey. Fore- and hindfeet brown. Tail relatively long (ca. 70% of HB), brown above, slightly paler below; pilosity 90%. Skull unspecialized; rostrum and maxillary medium, interorbit wide, braincase width medium, and braincase height high. First upper incisor long and hooked, third molar wide (cf. Vesmanis 1977). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded from only a few localities in Cyrenaica, Libya (Hutterer 1993).

Habitat Wadis and bushland with Mediterranean-type vegetation in the northern part of Cyrenaica.

Abundance No information.

Remarks Remains of this shrew were abundant in pellets of Barn Owls collected in Wadi al Kuf, Cyrenaica (R. Hutterer, unpubl.).

Conservation IUCN Category: Least Concern.

Crocidura allex EAST AFRICAN HIGHLAND SHREW

Fr. Crocidure des montagnes; Ger. Hochland-Spitzmaus

Crocidura allex Osgood, 1910. Field Mus. Nat. Hist. Publ., Zool. ser. 10 (3): 20. Kenya, 'Naivasha, British East Africa'.

Taxonomy Synonyms: *alpina*, *zinki* (see Heim de Balsac & Meester 1977). Subspecies: none. Gureev (1979) listed *alpina* as a distinct species without comment.

Description Small dark brown shrew. Pelage thick and dense, 3–4 mm dorsally. Dorsal pelage burnt umber, hairs dark grey, burnt umber at tip. Ventral pelage brownish-grey; hairs grey on basal half, brownish-grey on terminal half. Fore- and hindfeet dark brown, digits with sharp pointed claws. Tail relatively very long (ca. 82% of HB), dark brown, pilosity 40%. Rostrum short, maxillary width medium, and interorbital constriction wide. Braincase wide and of medium height. First incisor moderately long and hooked, third molar wide. Nipples: not known.

Geographic Variation Uncertain. Heim de Balsac (1957a) described a subspecies (*zinki*) from a high elevation (3550 m) on Mt Kilimanjaro, but this has not been recognized by subsequent authors.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the highlands of C Kenya (e.g. Mt Kenya, Aberdare Ranges, Mau Forest, Nanyuki – see Aggundey & Schlitter 1986) and N Tanzania (Mt Kilimanjaro, Mt Meru and Ngorogoro Crater).

Habitat Occurs from the forest to the alpine zones (Grimshaw *et al.* 1997). On Mt Meru collected in the bamboo zone between 2550 and 2750 m (Demeter & Hutterer 1986). Recorded to at least 3700 m on Mt Kilimanjaro (Child 1965) and up to 4100 m on Mt Kenya (Coe & Foster 1972).

Abundance Rather common on Mt Kilimanjaro at 3500 m in habitats with highest ground cover (Shore & Garbett 1991). The second most abundant small mammal on the Shira Plateau (Mt Kilimanjaro), with densities of 2.9–5.8/ha (Shore & Garbett 1991). Not common on the montane grasslands of Mt Kilimanjaro (W. N. Verheyen pers. comm. 2003).

Remarks On Mt Kenya, found on pathways made by *Otomys* spp. (Otomysinae: Rodentia) (Coe & Foster 1972). One pregnant ♀ found on Mt Kilimanjaro (17 Jul–7 Aug; n = 23 shrews; Shore & Garbett 1991). Remains of *C. allex* were found in faeces of Servals *Leptailurus serval* in Ngorogoro Crater, Tanzania (Geertsema 1985). Raptors may also be predators.

*Crocidura allex*

Conservation IUCN Category: Vulnerable.

Crocidura ansellorum ANSELL'S SHREW

Fr. Crocidure des Ansell; Ger. Ansell's Spitzmaus

Crocidura ansellorum Hutterer and Dippenaar, 1987. Bonn. Zool. Beitr. 38: 1 (see also below).

Kasombu stream (= Isombu River), Mwinilunga Distr., Zambia. 4100 ft.

Taxonomy The species was originally named *C. anselli* but was emended to *C. ansellorum* (Hutterer & Dippenaar 1987b). The phylogenetic relations of the species are unknown. Synonyms: none. Chromosome number: not known.

Description Very small shrew. Pelage soft, hairs ca. 4 mm. Dorsal pelage dark chocolate-brown. Ventral pelage slightly washed with greyish-brown (most notable on the throat of the holotype). Limbs and ears dark chocolate-brown. Tail relatively long (ca. 80% of HB), greyish-brown; pilosity ca. 51%. Skull broad and high-domed. Upper incisor long and hooked. First unicuspid large and pointed, second and third subequal in size, all three with a well-developed cingulum. Third upper molar medium-sized. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded only from N Zambia; regarded as endemic to the Ikelenge Pedicle, NW Zambia (Cotterill 2002b).

Habitat Gallery forest along streams.

Abundance Rare; known from only three specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

N Zambia (Hutterer & Dippenaar 1987a)

Key References Cotterill 2002b; Hutterer & Dippenaar 1987a.**Rainer Hutterer***Crocidura attila* HUN SHREW (CAMEROON SHREW)

Fr. Crocidure du Cameroun; Ger. Hunnen-Spitzmaus

Crocidura attila Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 512; ser. 8, 16: 141. Bitye, South Cameroon. 2000 ft.

Taxonomy Originally described as a subspecies of *C. poensis*; included in *C. buettikoferi* by Heim de Balsac & Meester (1977) but now considered to be a distinct species (Hutterer & Joger 1982). Very similar to *C. poensis*. Synonyms: none. Chromosome number: 2n = 50, FN = 66 (Cameroon; Schlitter *et al.* 1999).

Description Medium-sized shrew. Dorsal pelage brown, paler laterally with fairly abrupt transition to paler ventral pelage; lateral gland silvery-white. Dorsal surface of fore- and hindfeet bicoloured.

Tail relatively short (55–65% of HB), dark brown above, paler below; pilosity 85–90%. Skull: second and third unicuspid subequal in size, third upper molar moderately broad. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Montane habitats in Rainforest BZ. Found on Mt Cameroon and the Adamaoua Highlands near Banyo, Cameroon (Heim de Balsac 1957b, Hutterer & Joger 1982).

and in the Gote Mts, SE Nigeria at 1900 m (Hutterer *et al.* 1992b). Perhaps extends eastwards from Nigeria/Cameroon border to E DR Congo (Hutterer *et al.* 1992b, Wolsan & Hutterer 1998). Eastern part of range needs confirmation.

Habitat Primarily montane forests.

Abundance No information.

Remarks Principal prey probably comprises a range of common invertebrates. Principal predators likely to be owls, reptiles and small carnivores such as mongooses, genets and small cats, which are known to feed on shrews.

Conservation IUCN Category: Least Concern.

Formerly considered as Vulnerable. Major threats are human-induced habitat loss and degradation.

Crocidura baileyi BAILEY'S SHREW (SIMIEN SHREW)

Fr. Crocidure de Bailey; Ger. Baileys Spitzmaus

Crocidura baileyi Osgood 1936. Field Mus. Nat. Hist., Zool. ser. 20 (21): 225.

Ras Dashan, Simien Mts, Ethiopia. 3400 m (ca. 13° 14'N, 38° 25'E).

Taxonomy Specimens recorded as *C. baileyi* by Osgood (1936) and Yalden *et al.* (1976) are now allocated to *C. lucina* (Dippenaar & Meester 1989). A member of the endemic Ethiopian *C. glassi* complex (*C. glassi*, *C. lucina*, *C. thalia*, *C. macmillani* and *C. baileyi*) (Dippenaar & Meester 1989). Synonyms: none. Chromosome number: not known.

Description Medium-sized *Crocidura* with a distinctly bicoloured pelage and tail. Pelage long, woolly and soft. Dorsal pelage brownish to reddish-brown; hairs grey at base, rufous at tip. Ventral pelage creamy-white, hairs grey at the base, white at tip. Dorsal surface of fore- and hindfeet whitish. Tail of medium relative length (ca. 51% of HB), brown above and whitish below; pilosity 100%. Skull with inflated braincase, as typical for the high altitude Ethiopian *Crocidura*. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ. Recorded only in Ethiopia in the highlands west of the Ethiopian Rift Valley (Simien Mts, Amedamit Mts, Enjiabara, Debre Sina and Ankober), 2700–3550 m.

Habitat Humid localities with tall grasses in afroalpine moorland and humid heather forest (Guttinger *et al.* 1998).

Abundance Relatively common in suitable habitats. Comprised 9.8% (17 of 173) of small mammals caught in the Simien Mts (Guttinger *et al.* 1998).

Remarks Woolly fur and relatively short tail might be adaptations to the cold at high altitudes. Presumed to be insectivorous or omnivorous.

Conservation IUCN Category: Endangered.

*Crocidura baileyi*

Previously considered as Vulnerable. Populations conserved within the Simien Mountains N. P.

Crocidura batesi BATES'S SHREW

Fr. Crocidure de Bates; Ger. Bates Spitzmaus

Crocidura batesi Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 143. Como River, Gabon.

Taxonomy Often included in *C. poensis* (Hutterer 2005b). Specimens from Cameroon and Gabon recorded as *C. wimmeri* belong to this species. Synonyms: none. Chromosome number: 2n = 50, FN = 76 (Schlitter *et al.* 1999).

Description Small to medium-sized dark chocolate-brown shrew. Dorsal pelage uniform dark chocolate-brown; hairs greyish-brown at base; chocolate-brown at tip. Ventral pelage similar to dorsal pelage or slightly paler. Upper surface of fore- and hindfeet brownish. Tail relatively long (ca. 60–75% of HB), brown above, paler below; pilosity ca. 20–60%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (Gabon sub-region). Known only from S Cameroon, Gabon, Equatorial Guinea (Rio Muni) and SW Central African Republic (Hutterer 1993, Ray & Hutterer 1995). Perhaps occurs in N Congo. Distribution limits uncertain.

Habitat Lowland rainforest. Recorded at all three altitudinal zones (110 m, 375 m, 625 m) on Mt Doudou, Gabon; seems to have preference for lower and wetter habitats near river margins (Goodman & Hutterer 2004).

Abundance Uncommon or rare. Represented 1.2% (2 of 160; 11 spp.) of captures in Belinga-Makokou, Gabon (Brosset 1988), 11.2% at Mt Alen, Equatorial Guinea (Lasso *et al.* 1996), 11.1% in

*Crocidura batesi*

Ngotto Forest, Central African Republic (Barrière & Nicolas 2000) and 9% in SW Gabon (Nicolas *et al.* 2003). On Mt Doudou, Gabon, found at four of nine localities sampled; where found, comprised 6–17% of all shrews (1 of 16, 8 spp.; 1 of 6, 5 spp.; 1 of 11, 6 spp.; 1 of 8; 3 spp.) (Goodman & Hutterer 2004).

Remarks Found in 3.2% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995, Ray 1998). One ♀ caught in Feb contained two small embryos (label, BMNH; Dja R., Cameroon).

Conservation IUCN Category: Least Concern.

Crocidura bottegi BOTTEGO'S SHREW

Fr. Crocidure de Bottego; Ger. Bottegos Spitzmaus

Crocidura bottegi Thomas, 1898. Ann. Mus. Civ. Stor. Nat. Genova, ser. 2, 18: 677. 'Between Badditu and Dime', NE L. Turkana, Ethiopia.

Taxonomy West African populations previously allocated to *C. bottegi* (Hutterer & Happold 1983) are now considered to represent *C. obscurior*. Synonyms: none. Chromosome number: not known.

Description Minute shrew. Dorsal pelage rich chocolate-brown with russet tinge. Ventral pelage slightly paler. Ears dark brown. Fore- and hindlimbs with brown hairs; claws short. Tail of medium relative length (ca. 60% of HB); pilosity ca. 80%. Skull with high and rounded braincase, rostrum short, interorbital and maxillary region short but wide. Front dentition weak. Third upper molar rather wide. Nipples: not known.

Geographic Variation None recorded. Populations from Ethiopia should be compared with those from Kenya.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known from three localities in the highlands of Ethiopia (Yalden *et al.* 1976) and from Marsabit, N Kenya (Aggundey & Schlitter 1986).

Habitat No detailed habitat information is available.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Crocidura bottegi

***Crociodura bottegoides* BALE SHREW (TRICOLOURED PYGMY SHREW)**

Fr. Crocidure de Bale; Ger. Bale Spitzmaus (Dreifarbige Zwergspitzmaus)

Crociodura bottegoides Hutterer and Yalden, 1990. In: Vertebrates in the Tropics (eds G. Peters & R. Hutterer), Bonn, p. 67. Katcha Camp, Harenna Forest, Bale Mts, Ethiopia. 2400 m.

Taxonomy Synonyms: none. Chromosome number: $2n = 36$, $FN = 60$ (Lavrenchenko *et al.* 1997).

Description Very small shrew with tricoloured pelage. Narrow dark brown band (6–8 mm) runs from top of the head along mid-back towards tail, bordered on each side by a yellowish-brown band of about the same breadth. Ventral pelage, limbs and tail creamy-brown (two specimens) or reddish-brown (one specimen). Claws short. Tail relatively very long (ca. 82% of HB); pilosity 0%. Braincase high and rounded, rostrum short and broad, interorbit and maxillary region short but wide. Dentition gracile, particularly the first upper incisor. Third upper molar medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Known only from two regions in Ethiopia: Harenna Forest in the Bale Mts, and Mt Albasso, Arussi (Hutterer & Yalden 1990, Yalden & Largen 1992, Lavrenchenko *et al.* 1997). Allopatric to *C. bottegi* (of similar size), which is also an Ethiopian endemic.

Habitat Relict forests. Found in a grassy clearing in *Schefflera* / *Hagenia* forest at 2400 m, and beneath a log in *Erica arborea* woodland at 3280 m (Hutterer & Yalden 1990). A larger species, *C. harenna* (mean WT: 7.8 g,) also lives in Harenna Forest, but in forested habitats.

Abundance Appears to be uncommon in Harenna Forest (Yalden 1988).

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

***Crociodura buettikoferi* BÜTTIKOFER'S SHREW**

Fr. Crocidure de Büttikofer; Ger. Büttikofers Spitzmaus

Crociodura buettikoferi Jentink, 1888. Notes Leyden Mus. 10: 47. Robertsport, Liberia.

Taxonomy This species formerly included *attila*, now regarded as a separate species (Hutterer & Joger 1982). Referred to as *Crociodura occidentalis nigeriae* by Sanderson (1940) and Cozens & Marchant (1952) (see Hutterer & Happold 1983). The specimen ascribed to this species from Oda, Ghana (Heim de Balsac 1958) is, in fact, *C. poensis* (Grubb *et al.* 1998). Synonyms: none. Chromosome number: not known.

Description Medium-sized dark-coloured shrew. Dorsal pelage dark chocolate-brown. Ventral pelage paler, greyish-brown. Limbs dark. Tail relatively long (ca. 70% of HB), dark, very sparsely covered with hairs and bristles; pilosity ca. 50%. Skull with a slightly domed braincase, nearly oval in dorsal view; skull smaller and more slender than in sympatric *C. poensis*. Upper first incisor medium and hooked. First unicuspid larger than second and third.

Third molar large. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (Western Region and Western Nigeria sub-region). Recorded from S Guinea, Liberia, Côte d'Ivoire, Ghana and Nigeria. Two specimens from Njala, Sierre Leone, and specimens from Wenchi, Ghana are perhaps this species (Grubb *et al.* 1998). Presence in Guinea-Bissau is uncertain.

Habitat Grassland habitats within the Rainforest BZ (rather than rainforest itself), forest relicts in derived savanna, secondary growth, cocoa plantations and cleared land.

Abundance Very varied, according to locality and habitat. In three sacred groves on the Accra plains, Ghana, only one individual was found out of a total of 14 shrews of four species of *Crocidura* (Decher & Bahian 1999). At Umuahia, Nigeria, it was considered to be 'one of the commonest ground-living mammals', and at Owerri, Nigeria, 32 specimens were obtained (Cozens & Marchant 1952). In Tai N.P., Côte d'Ivoire, comprised 13% and was the fourth commonest species of shrew (10 spp.) (Churchfield *et al.* 2004). In another study in Tai N.P., uncommon in forest (7.2% of 390 shrews, 9 spp.) but one of the two most abundant species in cocoa-coffee plantations (29.3% of 140 shrews, 7 spp.) (Barrière *et al.* 1999). In Ziama Biosphere Reserve, Guinea, uncommon in primary forest, secondary forest, fields, fallow land and young forest plantations (4.8%–13.2%), but the commonest species (36.4% of 441 shrews, 9 spp.) in old forest plantations (P. Barrière unpubl.).

Remarks In Tai N. P., Côte d'Ivoire, commonest prey items (% frequency of occurrence) in 28 stomachs were representatives of the following taxa: Araneae (46%), ants (46%), adult Coleoptera (36%), Isoptera (32%), Diplopods (18%), Blattodea (18%), Gryllidae (14%), Diptera larvae (11%) and earthworms (11%). Several other taxa were each represented by frequencies of <10%. Most (82%) of the prey were 15 mm or less in length (Churchfield *et al.* 2004).

Conservation IUCN Category: Near Threatened.

Crocidura caliginea AFRICAN DUSKY SHREW (DUSKY WHITE-TOOTHED SHREW)

Fr. Crocidure sombre; Ger. Dunkle Weißzahnschmaus

Crocidura caliginea Hollister, 1916. Bull. Am. Mus. Nat. Hist. 35: 664. Medje, NE DR Congo.

Taxonomy In skull characters resembles *C. yankariensis* (Hutterer & Jenkins 1983). It also shares unusual characteristics with *Paracrocidura schoutedeni* (Hutterer & Duda 1990). Synonyms: none. Chromosome number: not known.

Description Small to medium-sized dark-brown shrew. Pelage 3.5 mm (on back). Dorsal pelage dark brown. Ventral pelage dark brown. Snout, ears, fore- and hindfeet covered by very short whitish hairs that contrast sharply with the uniformly dark pelage of the body. Ear small relative to head, pale, covering only half the height of the head. Hindfeet relatively short. Tail relatively long (70%

of HB), brown; pilosity 20–30%. Skull strongly built, with heavy maxillary processes. The skull differs from the general *Crocidura* type by its rectangular shape, broad maxillary region and narrow interorbital region and long rostrum. Teeth comparatively large and well developed. First upper incisor long and hooked. Second upper incisor (= first unicuspid) most unusual in being twice as large as the second and third upper unicuspid, and in having (mostly in ♂♂) a secondary cusp. Upper molars large. Molar teeth of mandible very well developed. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (East Central Region) of NE DR Congo. Until 1990, recorded from only two localities (Medje [type locality] and Masako Forest [near Kisangani]) (Hollister 1916, Hutterer & Dudu 1990), but has since been found to occur in various forests in the vicinity of Kisangani (Mukinzi *et al.* 2006). The geographic range of the species still appears to be very limited.

Habitat In Masako Forest, most *C. caliginea* have been found in secondary forest (40-year-old regrowth) surrounded by primary forest (mono-dominant *Gilbertiodendron* forest). Some have been found in fallow land and in moist areas along creeks (Hutterer & Dudu 1990, Dudu *et al.* 2005). In recent surveys near Kisangani (Mukinzi *et al.* 2006, and unpubl.), it has been found also in primary forest.

Abundance Considered a rare, endemic species but may be relatively abundant locally. Numerically the commonest species during three years of trapping in Masako Forest where it comprised 47% of shrews in secondary forest ($n = 36$; 8 spp.) and 33% of shrew captures in all habitats ($n = 72$, 9 spp.) (Dudu *et al.* 2005).

Adaptations External characters of *C. caliginea* suggest a terrestrial species with some modifications towards a semi-fossorial life. Large, heavy teeth are particularly well adapted for crushing tough, chitinous exoskeletons of arthropods.

Foraging and Food Feeds on a wide range of invertebrates, primarily arthropods. Stomach analyses ($n = 20$) from rainforest in Masako Forest showed that Formicidae were major prey items (100% by frequency), followed by Isoptera (60%), Araneae (60%), adult Coleoptera (55%) and Diplopoda (45%). Invertebrate prey ranged in body length from 3 mm to 20 mm with 85% being <10 mm (Dudu *et al.* 2005).

Social and Reproductive Behaviour No information. The possession of an additional cusp on the second upper incisor in significantly more ♂♂ than ♀♀ (see above) suggests partial sexual dimorphism, which would be most unusual in the Soricidae.

Reproduction and Population Structure No information.

Predators and Diseases No information but principal predators likely to be owls and small mammalian carnivores such as mongooses, genets and small cats known to feed on shrews (Demeter 1981, Ray & Hutterer 1995).

Crocidura caliginea

Conservation IUCN Category: Least Concern.

Formerly assessed as Critically Endangered. A rare endemic species with a very restricted range. Major threats are human-induced habitat loss and degradation of the rainforests.

Crocidura cinderella CINDERELLA SHREW

Fr. Crocidure cendr  e; Ger. Cinderellas Spitzmaus

Crocidura cinderella Thomas, 1911. Ann. Mag. Nat. Hist., ser. 8, 8: 119. 'Gemenjulla, French Gambia' (= Senegal).

Taxonomy The species may be related to *C. tarfayensis* of Morocco and Mauritania (Hutterer 1987). Synonyms: none. Chromosome number: not known.

Description Very small to small pale-coloured shrew. Pelage short (ca. 2 mm) and dense. Dorsal pelage brownish-grey; hairs dark grey on basal two-thirds, pale cream or pale brown subterminally, with russet-brown to pale brown at tip. Ventral pelage pale grey;

hairs grey at base, white at tip. Colour of ventral pelage delineated from dorsal pelage on lower flanks, especially from shoulder to base of tail. Chin, throat and chest grey. Fore- and hindfeet white; claws transparent, pointed and sharp. Tail relatively long (ca. 70% of HB), bicoloured, pale brown above, white below; pilosity ca. 80%. Skull with flat dorsal roof and flat braincase. Rostrum, interorbital and braincase of medium length, maxillary wide. First incisor long and hooked. Third molar medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sudan Savanna and Sahel Savanna BZs of West Africa. Known from scattered localities in Senegal, Mauritania, Gambia, Mali and Niger (Hutterer 1993).

Habitat A specimen from Bandia, Senegal, was collected in dry *Acacia seyal* forest (Böhme & Hutterer 1978); another in a banana plantation at Keur Moussa monastery. *Crocidura cinderella* shares these habitats with *C. fuscomurina*, *C. lamottei*, *C. lusitania* and *C. olivieri* (R. Hutterer unpubl.).

Abundance Appears to be rare. Known from fewer than ten specimens.

Remarks The flat skull and the pale grey pelage perhaps indicates an adaptation to life in rocky fissures in arid habitats.

Conservation IUCN Category: Least Concern.

Crocidura congobelgica CONGO SHREW (CONGO WHITE-TOOTHED SHREW)

Fr. Crocidure du Congo; Ger. Kongo-Weißzahnschmaus

Crocidura congobelgica Hollister, 1916. Bull. Amer. Mus. Nat. Hist. 35: 670. Lubila, near Bafwasende, NE DR Congo.

Taxonomy Probably related to sympatric *C. latona*, which it closely resembles in appearance (Hollister 1916); however, *C. congobelgica* has a larger skull, much wider palate, stronger maxillary processes and larger teeth, but lacks a fovea on the hypoconid of M₃ (present in *C. latona* and *C. caliginea*). Resembles sympatric *C. caliginea* in size and proportions but differs in colour, and is also very similar to *C. buettikoferi*. Synonyms: none. Chromosome number: not known.

Description Small-medium, unicoloured, dark-brown shrew. Dorsal pelage glossy dark-brown, finely streaked with cinnamon-buff. Ventral pelage slightly paler in colour. Fore- and hindfeet thinly clothed in brown hairs. Tail relatively long (ca. 75% of HB), brownish-black, paler underneath at base; nearly naked except for scattered short hairs; pilosity 25%. Skull with large maxillary processes. Unicuspid teeth rounded; first upper unicuspid relatively larger, oval in crown pattern, and with well-developed cingulum. Second and

third unicuspid similar to first and approximately equal in size; third unicuspid slightly overlapping the second. Last upper premolar lacks conspicuous posterior emargination, the median space between it and the first molar being very small; length approximately equal to its breadth. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Found only in NE DR Congo and probably endemic to this region. Latterly found in and around Masako Forest Reserve (NE of Kisangani) and in Ituri Forest (NE DR Congo).

Habitat Primary and secondary rainforest. Captured only in fallow land adjacent to rainforest in Masako Forest, DR Congo (Dudu *et al.* 2005).

Abundance Appears to have small, localized populations and is rare in trapped samples. Comprised 14% of shrews ($n = 21$; 6 spp.) in fallow land, and only 4% of shrews ($n = 72$; 9 spp.) in all habitats during three years of trapping in Masako Forest, DR Congo (Dudu *et al.* 2005).

Remarks A terrestrial, ground-dwelling species. Feeds on a wide range of invertebrates, primarily arthropods. Stomach analyses ($n = 3$) contained the following prey: Isoptera, Formicidae, Diptera and Lepidoptera larvae, Heteroptera, Araneae, Chilopoda and Diplopoda. Invertebrate prey ranged in body length from 3 mm to 30 mm but most were <10 mm (Dudu *et al.* 2005).

Conservation IUCN Category: Least Concern.

Species insufficiently known. Probably a species of conservation concern because of its very restricted distribution and small population numbers. At risk from habitat modification and isolation, particularly deforestation.

Crociodura crenata JUMPING SHREW

Fr. Crocidure sautante; Ger. Springende Weißzahnspitzmaus

Crociodura crenata Brosset, Dubost and Heim de Balsac, 1965. Mammalia 29: 268. Belinga, Gabon.

Taxonomy A comparison of 16s rRNA gene fragments reveals that *C. crenata* is closely related to *C. dolichura* (Quérouil *et al.* 2005). Synonyms: none. Chromosome number $2n = 48$ (Primus *et al.* 2006).

Description Small–medium sized, reddish-brown shrew with long hindfoot and long tail. Pelage short (hairs ca. 4 mm) and dense. Dorsal pelage and ventral pelage reddish-brown or russet-brown; hairs grey on basal half, reddish-brown on terminal half. Head similar in colour to dorsal pelage. Long vibrissae. Ears relatively large, darkly pigmented, not concealed by pelage. Fore- and hindfeet flesh-coloured, appear naked but with very short ginger hairs. Tail relatively extremely long (ca. 120% of HB, relatively longer than in most other *Crociodura* of similar size), dark brown, slightly bicoloured; pilosity 0%. Skull long and narrow. Rostrum long, wide and high. Maxillary and braincase narrow, interorbit wide. Braincase highly inflated. Dentition very weak (even compared to *C. dolichura*). First upper incisor short and slightly hooked. Third upper molar medium. Incisor of mandible has two denticles on inner surface. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Eastern Nigeria and Gabon sub-regions]). Recorded from S Cameroon, N Gabon, N Congo and S Central African Republic (Brosset 1988, Hutterer 1993, Hutterer & Schlitter 1996, Ray & Hutterer 1995, Goodman *et al.* 2001, Nicolas *et al.* 2003, Barrière *et al.* 2005). One possible record from Rainforest BZ (East Central Region).

Habitat Rainforest and marshy habitats in rainforest, mostly at lower altitudes; recorded from rainforest in ‘montagne’ at Belinga, Gabon (Brosset 1988).

Abundance Varies according to habitat and locality. At Mt Doudou, Gabon, found at three altitudes (110 m, 375 m, 625 m), and the second most common species of shrew (17%; 9 spp.) after *Sylvisorex johnstoni* (Goodman & Hutterer 2004). In another study, comprised 9.7% of shrews (14 of 144; 9 spp.) (Nicolas *et al.* 2003). In Minkébé Forest, Gabon, only one specimen was obtained (out of

11) in marshy habitats, and it was not present in drier parts of the forest (Goodman *et al.* 2001). Comprised 1.2% (2 of 160; 11 spp.) in NE Gabon (Brosset 1988).

Remarks Hindfeet extremely long in relation to body size, which may assist in jumping rather than climbing (Brosset 1988). Tail very long; may allow a scansorial life on vines and in dense vegetation; however, not caught in traps placed above ground at Mt Doudou (Goodman & Hutterer 2004).

Conservation IUCN Category: Least Concern.
Status insufficiently known.

Measurements

Crocidura crenata

Rainer Hutterer & Patrick Barrière

Crocidura crossei CROSSE'S SHREW

Fr. Crocidure de Crosse; Ger. Crosses Moschusspitzmaus

Crocidura crossei Thomas, 1895. Ann. Mag. Nat. Hist., ser. 6, 16: 53. 'Asaba, 150 miles [241 km] up the River Niger', Nigeria.

Taxonomy Resembles *C. gracilipes* in size and colouration. Heim de Balsac & Meester (1977) included *ebriensis*, *ingoldbyi* and *jouvenetae* in *C. crossei*, an arrangement followed by Hutterer (1993). However, Hutterer (2005b) considers the larger *jouvenetae* to represent a separate species (with *ebriensis* as a synonym). Sympatric with *C. juvenetae* for most of its range. Synonyms: *ingoldbyi*. Subspecies: none. Chromosome number: 2n = 44, FN = 66 (Côte d'Ivoire; Meylan & Vogel 1982; this karyology may be based on specimens of *C. crossei* or *C. juvenetae*).

Description Small shrew. Dorsal pelage slaty-grey or greyish-brown to chocolate-brown. Ventral pelage greyish and paler. Chin white. Limbs usually dark; fore- and hindfeet brownish-buff. Tail relatively very long (about 84% of HB), quite stout; grey-brown above, paler below; well furnished with small dark hairs and sparsely but evenly distributed with long bristles along most of its length; pilosity ca. 85%. Skull long, with a flat braincase. Dorsal profile of skull angular, sometimes with a marked mid-dorsal break (see also *C. douceti*). Rostrum slender, maxillary region narrow. Anterior upper incisors small and delicate; second and third upper unicusps approximately equal, their tips about level with the basal cusp of P⁴. Nipples: not known.

Geographic Variation Considerable variation in pelage colour from one locality to another, even within the same vegetation zone. Rainforest individuals are generally darker than those in forest–savanna mosaic habitats (Hutterer & Happold 1983).

Distribution Endemic to Africa. Rainforest BZ (Western Region and West Central Region), Northern Rainforest–Savanna Mosaic and Guinea Savanna BZ from Guinea and Sierra Leone to W Cameroon.

Habitat Forest habitats, including lowland rainforest, relic forests in savanna, and tree plantations (Hutterer & Happold 1983, Decher *et al.* 1997). Found at various altitudes, from closed canopy forests along the R. Niger to forests on Mt Cameroon.

Abundance In Gambari Forest, Nigeria, comprised 71% of shrews (2 spp., n = 56) trapped during three years; much more common than the other syntopic species (*C. nigeriae*) (Happold 1977).

Adaptations Primarily terrestrial but also clammers over fallen tree trunks and branches.

Foraging and Food No information, but searches for invertebrate prey in leaf litter, soil crevices and rotting wood.

Social and Reproductive Behaviour Low recapture rates suggest that individuals wander widely and do not remain in the same area for very long. Of 40 marked individuals in rainforest of S Nigeria, only four were captured a second time; of these, three were seen a second time within one month, and the fourth was seen again five months later (Happold 1977, 1987).

Reproduction and Population Structure Pregnant ♀♀ were found in the wet season (Apr, May, Oct and Nov) in S Nigeria (Happold 1977), and in early Dec in Ghana (Decher *et al.* 1997). Litter-size: 2–4 (Nigeria; Happold 1987).

Predators, Parasites and Diseases No information but principal predators likely to be owls, reptiles and small carnivores such as mongooses, genets and small cats known to feed on shrews.

Conservation IUCN Category: Least Concern.

A widespread and relatively common species of no immediate conservation concern.

Crociodura cyanea REDDISH-GREY SHREW

Fr. Crocitude de Cyané; Ger. Rotgraue Moschusspitzmaus

Crociodura cyanea (Duvernoy, 1838). Mem. Soc. Hist. Nat. Strasbourg. 'La rivière des Elephants, au sud de l'Afrique' (= Citrusdal, South Africa).

Taxonomy Originally described in the genus *Sorex*. Polytypic. The taxonomic limits of the species are uncertain; and many of the subspecies listed by Heim de Balsac & Meester (1977) are now considered as valid species, or as synonyms of other species. Some names, e.g. *infumata* and *cyanea*, are considered as subspecies by Meester *et al.* (1985), but as synonyms here. Synonyms: *argentatus*, *capensis*, *?capensoides*, *?concolor*, *electa*, *infumata*, *martensii*, *pondoensis*, *vryburgensis* (see Hutterer 2005b for details). Subspecies: none. Chromosome number: not known.

Description Small–medium (♀♀) to medium-sized (♂♂) shrew. Dorsal pelage brownish-grey, grizzled with pale yellow; hairs

slaty-grey at base, with pale-grey or yellowish subterminal bands and brown tip. Ventral pelage paler grey with a yellow or brown tinge in older specimens; hairs slaty-grey at base with silvery-grey tip. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet yellow to pale brown; each with five digits. Tail relatively long (ca. 69% of HB), pale to dark brown above; paler below; pilosity ca. 50%. Males on average larger than ♀♀. Nipples: 0 + 3 = 6.

Geographic Variation Western forms are generally paler than the eastern ones. There is also variation in size in different parts of the range.

Distribution Endemic to Africa. Widespread in Zambezan Woodland BZ and South-West Arid BZ (but excluding much of the Kalahari Desert). Recorded from N Zambia and N Mozambique southwards to southern Africa, and then northwards through C Namibia. Conspicuously absent from E Namibia, N Botswana, N–C Karoo and C Mozambique.

Habitat Montane forest and grassland, vleis, dense shrubs, savanna, grasslands and rocky outcrops. Has a remarkably wide habitat tolerance.

Abundance Widespread and comparatively common in some areas.

Adaptations Predominantly nocturnal and terrestrial. In C Namibia, there is a cave-dwelling population where individuals penetrate 150 m into the cave, apparently thriving on the numerous invertebrates, such as ptinid beetles, apterous crickets and pseudoscorpions that are found there (Marais & Irish 1990). Shrews were collected from areas in the cave where large numbers of bats roost, and may well feed on carcasses that are fairly common at those sites.

Foraging and Food Insectivorous (Monadjem 1997).

Social and Reproductive Behaviour Solitary.

Reproduction and Population Structure In South Africa, reproductive activity occurs during the wet season (Sep–Apr) (Rautenbach 1982, Lynch 1983, Skinner & Smithers 1990). In KwaZulu–Natal Province, South Africa, a pregnant specimen was collected during the dry season (Jul) (Taylor, P. 1998). Probably breeds opportunistically. Mean litter-size: 3.3 (range 2–6; mode 4; n = 12) (Rautenbach 1982, Lynch 1983, Taylor, P. 1998).

Predators, Parasites and Diseases Remains of this species have been recovered from the pellets of Barn Owls *Tyto alba*.

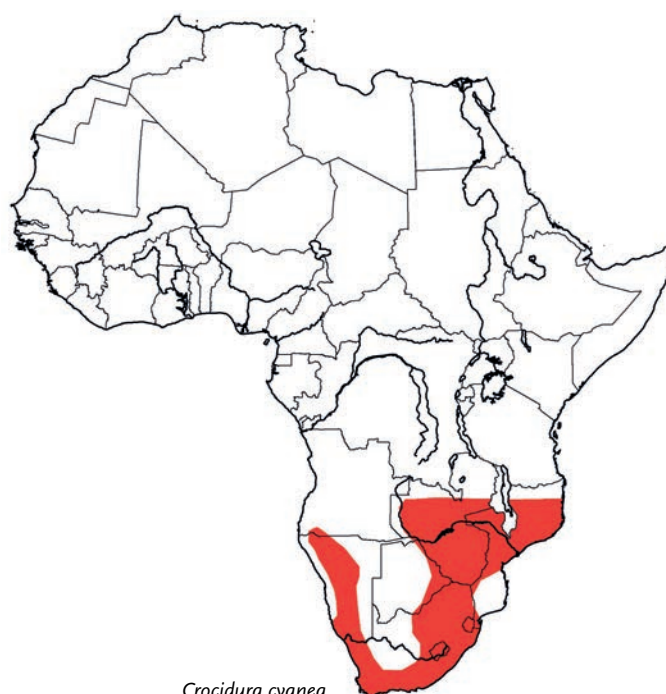

Conservation IUCN Category: Least Concern.
A relatively common shrew.

Crociodura denti DENT'S SHREW (DENT'S WHITE-TOOTHED SHREW)

Fr. Crociodure de Dent (Crociodure d'Ituri); Ger. Dents Spitzmaus

Crociodura denti Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 377. Between Mawambi and Avakubi, Ituri Forest, DR Congo.

Taxonomy Originally described as a subspecies of *C. jacksoni*. West African records for this species (Ziegler *et al.* 2002) need confirmation. Preliminary genetic data suggest that the species is composite and perhaps includes more than one species (Quérroul *et al.* 2005). No synonyms. Chromosome number: not known.

Description Small dark brown shrew with hairy tail. Dorsal pelage dark brown. Ventral pelage slate-grey. Tail relatively long (ca. 65–70% of HB), brown above, paler below; pilosity 66–75%. Skull stout with short and broad snout. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ; widespread but disjunct. Recorded from Cameroon, Gabon and NE DR Congo; may occur in N Congo. Records from Guinea and Sierra Leone need confirmation (see above).

Habitat Swamp forest in Guinea (Ziegler *et al.* 2002), gallery forest in montane savanna in Adamoua Highlands, Cameroon (Hutterer & Joger 1982), secondary forest in Masako Forest Reserve (Dudu *et al.* 2005).

Abundance The most common shrew captured by owls (25% of 64) in the Adamaoua Highlands, Cameroon (Hutterer & Joger 1982). Formed 19.4% of shrew captures ($n = 72$) in Masako Forest, DR Congo (Dudu *et al.* 2005). Elsewhere, rarely captured.

Remarks Stomach analyses from rainforest in Masako Forest showed that Isoptera were major prey items (30% by composition), followed by Diplopoda (13.6%), Formicidae (11.4%), Coleoptera (9.6%), Araneae (8.5%), Blattoidea (6.0%), Heteroptera (5.5%), Lepidoptera (5.5%), Diptera larvae (4.3%) and Acrididae (<1%) (Dudu *et al.* 2005). Remains of this species were found in 2.9% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995; Ray 1998).

Conservation IUCN Category: Least Concern.

Crocidura desperata DESPERATE SHREW

Fr. Crocidure triste; Ger. Rasende Spitzmaus

Crocidura desperata Hutterer, Jenkins and Verheyen, 1991. Oryx 25: 165. Rungwe Mts, S Tanzania. Above 2000 m.

Taxonomy Relationships of this shrew are still unresolved (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Medium-sized greyish-brown shrew. Pelage long, dense and woolly; dorsal hairs 10 mm. Dorsal pelage deep greyish-brown, slightly speckled. Ventral pelage pale grey. Colour of dorsal and ventral pelages merge. Fore- and hindfeet pale grey (as ventral pelage). Claws well developed: claws on forefeet 2.5–2.6 mm, claws on hindfeet 2.6–2.9 mm. Tail relatively long (ca. 75% of HB), thick at base, bicoloured, brown above, grey below; pilosity 70–76%. Skull large, rather flat. First incisor long and hooked. Skull large, rostrum elongated, interorbital region narrow. Upper incisor long and gracile. First unicuspid larger, second and third unicuspid smaller and equal. Upper last molar small. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Known only from the Rungwe and Udzungwa (Uzungwa) Mts, S Tanzania. Not known from any of the other Eastern Arc Mts in Tanzania.

Habitat Bamboo zone and relict montane forests above 2000 m (Hutterer *et al.* 1991).

Abundance Extremely localized.

Remarks Some of the characteristics of the body, e.g. long claws on hindfeet (similar to those of *Myosorex* spp.), comparatively small ears and dorsal surface of hindfoot with small scales and relatively few hairs suggest that these shrews may be partly fossorial. Elongated incisors suggest that earthworms may form part of the diet (Hutterer *et al.* 1991).

Conservation IUCN Category: Endangered.

Measurements

Crocidura desperata

Crocidura desperata

Crocidura dolichura LONG-TAILED SHREW (LONG-TAILED MUSK SHREW)

Fr. Crocidure à queue longue; Ger. Langschwanz Spitzmaus

Crocidura dolichura Peters, 1876. Monatsb. K. Preuss. Akad. Wiss. Berlin 1876: 475. Bonjongo, Cameroon.

Taxonomy The taxa *latona*, *ludia*, *muricauda* and *polia* were included in *C. dolichura* by Heim de Balsac & Meester (1977) but are regarded as valid species by Hutterer & Dippenaar (1987a) and Hutterer (1993, 2005b). Sister taxon of *C. crenata* (Quérouil *et al.* 2005). Synonyms: none. Chromosome number: not known.

Description Small grey-brown shrew. Dorsal pelage uniform deep greyish-brown. Ventral pelage slightly paler grey. Hindfeet relatively short. Hind- and forefeet with scattered white hairs. Tail relatively extremely long (125–150% of HB); pilosity 0%. Skull laterally depressed and rounded, braincase oval. Dorsal profile with straight rostrum and inflated braincase. Dentition weak, I¹ and subsequent unicuspid very small; M³ large. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (West Central and East Central Regions). Recorded from S Nigeria, S Cameroon, N Gabon, S Central African Republic, DR Congo (N of Congo R.), Uganda and Burundi. Also Bioko I.

Habitat Primary and secondary rainforests over a wide range of altitudes. In E DR Congo, found in primary rainforests, secondary rainforests and montane forests (e.g. *Neoboutonia* and mixed forests), but not found in swamps or in cultivations (Dieterlen & Heim de Balsac 1979).

Abundance Uncommon. Proportional abundance varies from 4% to 9% depending on the shrew community and location. Comprised 4% of captured shrews at Mt Alen, Equatorial Guinea (n = 26; 8 spp.; Lasso *et al.* 1996), 4% at Mt Doudou, SE Gabon (n = 503; 9 spp.; Nicolas *et al.* 2004), 4.5% in SW Gabon at 110 m (n = 44; 9 spp.; Nicolas *et al.* 2004).

Crocidura dolichura

spp.; Goodman & Hutterer 2004), 7.5% at Belinga-Makokou, Gabon (n = 160; 11 spp.; Brosset 1988), 8% in Korup National Park, S Cameroon (n = 24; 9 spp.; Hutterer & Schlitter 1996) and 9% in marshland at Minkébé Reserve, Gabon (n = 11, 7 spp.; Goodman *et al.* 2001).

Remarks The long tail may be used for balance (Hutterer & Happold 1983). Embryo number: 2.5 (2–3, n = 2; Belinga-Makokou, Gabon; Brosset 1988). Stomach contents (n = 1) includes representatives of the following: Formicidae, adult Diptera, Lepidoptera larvae, Diplopoda and Araneae (Dudu *et al.* 2005). Found in 3.9% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995; Ray 1998).

Conservation IUCN Category: Least Concern.

Measurements

Justina C. Ray & Rainer Hutterer

Crocidura douceti DOUCET'S SHREW (DOUCET'S MUSK SHREW)

Fr. Crocidure de Doucet; Ger. Doucets Moschusspitzmaus

Crocidura douceti Heim de Balsac, 1958. Mem. Inst. Fr. Afr. Noire 53: 329. Adiopodoume, Côte d'Ivoire.

Taxonomy Very similar to *C. muricauda* but apparently not closely related; exact genetic relations unknown (Quérouil *et al.* 2005). Synonyms: none. Chromosome number: not known.

Description Very small shrew. Dorsal pelage greyish-brown to chocolate-brown; hairs uniformly coloured. Ventral pelage grey to off-white. Fore- and hindlimbs with pale hairs. Tail relatively long (ca. 80% of HB), dark and thin, with small hairs and dark bristles; pilosity 20%. Skull similar to *C. crossi* (dorsal profile flatter) and *C. muricauda* (skull larger); rostrum short. Upper and lower dentition weak, particularly the first incisor and unicuspid. M³ large. Nipples: not known.

Geographic Variation Dorsal pelage darker in northern populations. Heim de Balsac & Aellen (1958) remarked that specimens from Serédou, Guinea, had longer tails and differed in colouration from the typical form and could represent a 'slightly different race'. The phylogenetic relations between the populations from Guinea to Nigeria are unresolved.

Distribution Endemic to Africa. Primarily Guinea Savanna BZ and margins of Rainforest BZ (Western Region, Guinea); also coastal forest relicts (Côte d'Ivoire). Recorded from Guinea and Côte d'Ivoire (Hutterer 2005b). Records from Nigeria (Hutterer & Happold 1983) are questionable (and not mapped). Distribution limits uncertain.

Habitat Relict and riverine forests in savannas. Also found in mixed secondary forest and swampy areas in the Taï Forest (Churchfield *et al.* 2004), and in moist tall grass-forest habitats near Adiopodoumé, Côte d'Ivoire (Heim de Balsac & Aellen 1958). Also found in a relict forest at base of inselberg (Abuja, Nigeria) (D. C. D. Happold unpubl.).

Abundance Rarely collected and abundance usually low: comprised 7% of shrews (n = 194) caught in secondary forest of

Taï N. P., Côte d'Ivoire (Churchfield *et al.* 2004); 3.2% of shrews (n = 390; 9 spp.) in forest and 1.4% of shrews (n = 140; 7 spp.) in cocoa-coffee plantations in Taï N. P. (Barrière *et al.* 1999); 1% of shrews (n = 96) in the Mt Nimba area (Heim de Balsac 1958); 1.3% of shrews (n = 79) in lower Côte d'Ivoire (Heim de Balsac & Aellen 1958); and 3.6% (n = 303; 10 spp.) in forest plantations, 5.6% (n = 500; 11 spp.) in primary forest and up to 8.8% (n = 272, 9 spp.) in fields in Ziama Biosphere Reserve, Guinea (P. Barrière unpubl.).

Crocidura douceti

Adaptations The long tail may be a modification towards a scansorial life. A nest containing two juveniles was found some 10 m above ground in a cavity of a palm tree (Heim de Balsac & Vuattoux 1969), and another specimen was found in a glue trap in the canopy of Taï Forest (Churchfield *et al.* 2004).

Foraging and Food Feeds on a wide range of invertebrates, primarily arthropods. Stomach analyses ($n = 14$) from Taï N. P. showed that Formicidae were major prey items (50% by frequency of occurrence), followed by Coleoptera (29%), Araneae (29%), Isoptera (29%) and some other groups of minor importance. Invertebrate prey ranged in body length from 3–20 mm with ca. 80% being <10 mm (Churchfield *et al.* 2004).

Reproduction and Population Structure Embryo number: 2 ($n = 1$; Côte d'Ivoire; Heim de Balsac 1958).

Conservation IUCN Category: Data Deficient.

Crocidura eisentrauti EISENTRAUT'S SHREW

Fr. Crocidure d'Eisentraut; Ger. Eisentrauts Spitzmaus

Crocidura eisentrauti Heim de Balsac, 1957. Zool. Jahrb. Abt. Syst. Oekol. Geogr. Tiere 85: 616.
Johann-Albrecht-Hütte, 2900 m, Mt Cameroun, Cameroon.

Taxonomy This species is not conspecific with *C. vulcani* (*contra* Heim de Balsac 1957b; see Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Small-medium brown shrew. Pelage soft and dense; hairs 4–5 mm on mid-dorsal line. Dorsal pelage brown to soft reddish-brown; hairs grey on basal half, brown on terminal half. Ventral pelage greyish-brown; hairs grey at base, pale brown to greyish-brown or white at tip. Ears dark, anterior part partly concealed by hairs. Fore- and hindfeet brown or greyish-brown. Tail relatively long (ca. 79% of HB), bicoloured, brown above, pale or whitish below; pilosity 33–50%. Skull flattish rising slightly at posterior end. Upper incisor small and hooked. First unicuspid large and slightly pointed; second and third unicuspid subequal in size; all three with weakly developed cingulum. Third upper molar medium-sized. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only on Mt Cameroon, Cameroon (1850–3000 m).

Habitat At higher altitudes (Pic Isabel, ca. 3000 m), lives in alpine grasslands. Habitat at lower altitudes (e.g. Refugium, 2000 m) is 'Schefflera montane forest' (1400–2600 m).

Abundance Uncertain; at 3000 m, Heim de Balsac (1959a) found six specimens of this species, and one specimen of *Sylvisorex morio*.

Remarks Two pregnant ♀♀ at 3000 m in Apr; one contained two embryos (Heim de Balsac 1959a) and the other contained three embryos (labels ZFMK).

Crocidura elgonius ELGON SHREW

Fr. Crocidure du Mont Elgon; Ger. Elgon-Spitzmaus

Crocidura elgonius Osgood, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 369. Kirui, Mt Elgon, Kenya.

Taxonomy Originally described as a subspecies of *C. bicolor* (now *C. fuscomurina*) but regarded as a separate species by Heim de Balsac & Meester (1977) and Hutterer (1983b, 1993). Synonyms: none. Chromosome number: not known.

Description Small brown shrew with short hairs. Dorsal hairs ca. 2 mm; ventral hairs ca. 1.5 mm. Dorsal pelage brown; hairs brown along entire length. Ventral pelage dirty white speckled with grey; hairs dirty white, grey at base. Colour of dorsal pelage clearly delineated from ventral pelage. Ears prominent and devoid of long hairs. Forefeet pale relative to dorsal pelage. Hindfeet dark brown on the distal two toes and edge of foot; yellowish on the inside. Tail of medium relative length (ca. 55% of HB), bicoloured, dark above, pale below; pilosity ca. 66%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of eastern Africa. Recorded from Kenya (Cherangani Hills, Eldoret, Kisumu, L. Nakuru, Mt Elgon [holotype], Muguga, Nairobi) and Tanzania (East and West Usambara, Uluguru and Udzungwa

Mountains) (Aggundey & Schlitter 1986 [and references therein], Stanley *et al.* 1998, Swynnerton & Hayman 1951).

Habitat Disturbed habitats near montane forest and in other habitats in highlands. In the Udzungwa Mts, common in dry forests at 600 m and absent in wetter forests above 1000 m. Recorded in rotting vegetation at the edge of a swamp (Allen & Loveridge 1942).

Abundance The most numerous shrew in drier forests of the Udzungwa Mts (70% of the shrews observed; n = 23). In the East Usambara Mts, the most common shrew in tea plantations, but absent from samples taken in nearby fragments of montane forests (W.T. Stanley unpubl.).

Remarks Terrestrial and nocturnal. In a sample from forests of the Udzungwa Mts in Aug (1995), ♂ : ♀ ratio was 11 : 5, and age ratio was 1 juvenile : 4 adults (n = 10). Similar ratios were found in samples from the East and West Usambara Mts collected between Jul and Sep (between 1991 and 1993): ♂ : ♀ ratio was 3 : 1 (n = 20), and age ratio was 1 juvenile : 3 adults (n = 16) (W. T. Stanley unpubl.). Remains found in owl pellets collected at Nairobi and L. Nakuru, Kenya (Hutterer 1983b).

Conservation IUCN Category: Least Concern.

May be 'Vulnerable' because of fragmented distribution and decline in suitable habitat.

Crocidura elgonius

Crocidura erica HEATHER SHREW (ANGOLAN WHITE-TOOTHED SHREW)

Fr. Crocidure d'Angola occidental; Ger. Angola-Spitzmaus

Crocidura erica Dollman, 1915. Ann. Mag. Nat. Hist. ser. 8, 15: 514; ser. 8, 16: 145. Pungo Andongo, Angola.

Taxonomy Relationship to *C. nigricans* uncertain (Crawford-Cabral 1987) but listed as a distinct species (Hutterer 1993, 2005b). Resembles *C. hirta* in cranial dimensions. Synonyms: none. Chromosome number: not known.

Description Large pale-coloured shrew. Dorsal pelage pale grey faintly washed with brown. Flanks greyer, gradually merging with dull grey ventral pelage. Dorsal surface of feet greyish-white. Tail of medium relative length (56% of HB), finely haired, brown above, greyish-white below; pilosity 45%. Skull: second unicuspid larger than third; third upper molar medium in size; talonid of third lower molar reduced to a single cusp. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded only from W Angola (Heim de Balsac & Meester 1971, Hutterer 1993, 2005b).

Habitat No information. The holotype was found at 1098 m.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Major threats are human-induced habitat loss and degradation, and restricted distribution.

Crocidura fischeri FISCHER'S SHREW

Fr. Crocidure de Fischer; Ger. Fischers Spitzmaus

Crocidura fischeri Pagenstecher, 1885. Jahrb. Wiss. Anst., Hamburg 2: 34, pl. 1, f. 1–3. Nguruman, Kenya.

Taxonomy Most of the records for this species listed by Heim de Balsac & Meester (1977) are not this species (Hutterer 1986a). Synonyms: none. Chromosome number: not known.

Description Medium-sized shrew. Dorsal pelage bluish-grey with brownish tinge. Ventral pelage white; hairs grey on basal half, white on terminal half. Upper lips, throat, and behind ears white; fore- and hindfeet white; all hairs grey on basal half, white on terminal half. Tail of medium relative length (ca. 59% of HB in ♀♀; 53% of HB in ♂♂), pale pink (skin) thick at base, tapering towards

tip, pilosity 100%. Skull: upper first incisor long and hooked. First upper unicuspid very large, double the size of second and third unicuspids. Third upper molar small. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Only known from Nguruman in S Kenya (north of L. Natron) and Himo, N Tanzania.

*Crocidura fischeri*

Habitat Grasslands of *Acacia* savanna woodland where widely scattered *Acacia tortilis* are the dominant species of tree, and *Themeda*, *Hyparrhenia* and *Cenchrus* are the common grasses. Due to heavy grazing by livestock, the area becomes denuded during the dry season and when daytime temperatures may reach 40 °C.

Abundance Locally abundant forming 78% of shrew captures at Nguruman.

Remarks Terrestrial and nocturnal. In Jun (1998), seven individuals were captured; of the four ♀♀, three had a perforate vagina suggesting they were in reproductive condition. The three ♂♂ were not in reproductive condition.

Conservation IUCN Category: Data Deficient.

More information is required before a valid assessment can be given.

Crocidura flavescens GREATER RED SHREW (GREATER RED MUSK SHREW)

Fr. Crocidure grande; Ger. Afrikanische Riesenspitzmaus

Crocidura flavescens (I. Geoffroy, 1827). Dict. Class. Hist. Nat. 11: 324; Mem. Mus. Hist. Nat. Paris 15: 126.

‘La Cafrérie et le pays de Hottentots’ (= King William’s Town, South Africa).

Taxonomy Originally described in the genus *Sorex*. The name *flavescens* previously used for forms now considered as species or synonyms of other species, especially *C. oliveri*, e.g. *atlantis*, *bueae*, *darfurea*, *hedenborgiana*, *hera*, *manni*, *martiensseni*, *occidentalis*, *spurelli*, *sururæ*, *zuleika*. The name *flavescens* is now restricted to giant shrews from southern Africa. Synonyms: *capensis*, *cinnamomeus*, *knysnae*, *rutilus*. Subspecies: none. Chromosome number: 2n = 50 (South Africa; Maddalena *et al.* 1987).

Description Very large brown shrew. Dorsal pelage fawn to cinnamon-brown; hairs slaty-grey at base, pale subterminal band and brown tip. Ventral pelage pale grey or yellowish-grey; hairs dark grey at base, off-white to pale yellow at tip; ventral colour merges fairly abruptly with dorsal colour on flanks. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet fawn with five digits. Tail of medium relative length (ca. 49% of HB), brown above, pale grey below; covered with sparse long hairs; pilosity ca. 65–80%. Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Distribution Endemic to Africa. Occurs in several biotic zones close to the coast of South Africa, and parts of the Highveld BZ. In South Africa, recorded along the escarpment of E Mpumalanga Province, the coastal regions of Western Cape and Eastern Cape Provinces, and throughout most of KwaZulu–Natal. Also recorded in E Lesotho, Swaziland and the Inhambane district of S Mozambique (Meester 1963, Meester *et al.* 1986, Monadjem 1998a, c, Taylor, P. 1998).

Habitat Usually occurs close to water where there is adequate ground cover. Trapped in a variety of vegetation types including fynbos, grasslands (montane, temperate and sub-tropical), coastal forest, woodlands, savanna and disturbed habitats in higher rainfall regions of South Africa. Commensal with humans and enters dwellings. Wide habitat tolerance.

Crocidura flavescens

Abundance Relatively common especially in sub-tropical habitats of its range. Very abundant in gardens in Pietermaritzburg, South Africa.

Adaptations Predominantly nocturnal with greatest peak of activity at dawn and a secondary peak at dusk (Baxter *et al.* 1979). Enters spontaneous torpor (Baxter 1996) during adverse environmental conditions, but exhibits no other special physiological adaptations (Brown *et al.* 1997). Very high levels of aggression (Baxter & Irwin 1995) assist it in killing vertebrate prey larger than itself.

Foraging and Food Feeds opportunistically on invertebrates and vertebrates; cannibalistic and also a scavenger. Diet includes insects, snails, earthworms, reptiles and rodents (Baxter 1977).

Social and Reproductive Behaviour Aggressive and territorial with probable overlap of male and female territories (Baxter & Irwin 1995). Territories are probably demarcated through scent-marking using lateral, chin and ano-genital glands and strongly scented faecal piles (Baxter & Meester 1982).

Vocalization includes (a) a loud, strident squeak when alarmed, (b) squeaks interspersed with 'chirrs' or chattering sounds during aggressive encounters, (c) chattering in female-young interactions and (d) soft, repetitive squeaks when foraging (Baxter & Meester 1982). Although vocalization has ultrasonic properties (up to 50 kHz), it is not used for echolocation (Irwin & Baxter 1980). Grooming behaviour includes scratching with the hindfeet, face-washing and occasionally licking of the pelage. Stretching and yawning have also been observed. Licking of the everted rectum and coprophagy are common behaviours (Baxter & Meester 1982).

Mating behaviour includes 'flehmen' when the ♂ sniffs the ano-genital region of the female (Baxter 1981), and chases last for up to 35 minutes. During the chasing, the ♀ occasionally pauses and the ♂ attempts to mount. Eventually the ♂ bites the rump of the ♀ and

she stops. Successful intromission lasts for seven seconds with the male biting strongly on her mid-back. After ejaculation, this grip is released and the ♀ moves off, dragging the male by his penis for a short period. After disengagement, the ♀ is usually aggressive towards the ♂ (Baxter & Meester 1982). Nests are spherical or saucer-shaped, often placed in rock crevices or under cover. Lactating ♀♀ show no aggression to strange young and will foster them (Baxter 1993a).

Reproduction and Population Structure Pregnancies occur during late dry season and wet season (Aug–Apr), but mostly in Oct–Dec. Gestation: ca. 28 days. Mean litter-size: 3.65 ($n = 51$), commonly 4. At birth: HB: 36.3 mm, T: 11.1 mm, HF: 6.2 mm, E: 2.5 mm, weight 1.8 g ($n = 186$). Young born naked, blind and helpless but development is rapid. Weaning at Day 18–22; by Day 28 young are adult size in all measurements except weight. Walking begins ca. Day 5, when caravanning first observed. Eyes and ears open ca. Day 12. Full pelage present ca. Day 14. Caravanning ceases ca. Day 16. Young leave nest ca. Day 28 (R. M. Baxter unpubl.). Young displaced from nest emit a high-pitched squeak after which they are retrieved by the female and carried in her mouth back to the nest. Females have a postpartum oestrus and litters can be conceived consecutively. Maturity usually attained by Day 90, but might occur as early as Day 28. Longevity 14–18 months in the wild but can be 2.5 years in captivity (R. M. Baxter unpubl.).

Predators, Parasites and Diseases Known predators include Banded Mongooses *Mungos mungo* (Baxter 1993b), Water Mongooses *Atilax paludinosus*, Zorillas *Ictonyx striatus*, Striped Weasels *Poecilogale albinucha* and two species of owl. Domestic cats capture but seldom consume these shrews (Baxter 1977).

Conservation IUCN Category: Least Concern.

A common shrew in urban gardens over much of its range.

R. M. Baxter & N. J. Dippenaar

Crocidura floweri FLOWER'S SHREW

Fr. Crocidure de Flower; Ger. Flowers Spitzmaus

Crocidura floweri Dollman, 1915. Ann. Mag. Nat. Hist. ser. 8, 15: 515; 1916 Ann. Mag. Nat. Hist., ser. 8, 17: 192. Giza, Egypt.

Taxonomy Hutterer & Harrison (1988) suggested that this species may be related to *C. arabica* (a non-African species) and *C. crossei*. Synonyms: none. Chromosome number: not known.

Description Small shrew. Dorsal pelage pale cinnamon-brown. Ventral pelage paler to whitish; hairs grey at base, white at tip. Abrupt delineation laterally of dorsal and ventral colours. Feet dirty white. Tail relatively long to very long (75–100% of HB), cinnamon-brown above, whitish below; bristle hairs bicoloured; pilosity 50%. Skull: second and third unicuspid subequal; third upper molar moderately broad; talonid basin present on third lower molar. Molars with a metaloph and metaconule (Heim de Balsac & Mein 1971). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sahara Arid BZ. Recorded from Nile Delta and El Faiyum (Osborn & Helmy 1980), and Wadi el Natrun, Egypt (Goodman 1989). Unconfirmed record in S Sudan (Wolsan & Hutterer 1998). Also identified in ancient mummified remains at Thebes in S Egypt (Heim de Balsac & Mein 1971).

Habitat Unknown except that specimens have been collected in fields.

Abundance No information.

Remarks Little information available. One specimen was obtained from the stomach of a cattle egret (Flower 1932, in Osborn & Helmy 1980) and another from regurgitated pellets of a Little Owl *Athene noctua* at Wadi el Natrun.

Conservation IUCN Category: Data Deficient.

Major threats are human-induced habitat loss and degradation, and restricted distribution.

Crocidura foxi FOX'S SHREW

Fr. Crocidure de Fox; Ger. Foxs Moschusspitzmaus

Crocidura foxi Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8., 15: 514. Panyam, Nigeria.

Taxonomy Considered as a member of the *poensis* group, and probably closely related to *C. theresae* (see Hutterer & Happold 1983, Hutterer 2005b). A series from Owerri, S Nigeria, referred to *C. foxi* by Hutterer & Happold (1983) now considered to represent a dark form of *C. lamottei*. Synonyms: *tephra*. Subspecies: none. Chromosome number: not known.

Description Large to very large shrew. Dorsal pelage chocolate-brown to russet-brown; hairs grey at base with brown tip. Ventral pelage grey; hairs grey, sometimes white at tip. Colour of ventral pelage well delineated from colour of dorsal pelage. Flanks, chest and throat grey. Tail relatively short (50–63% of HB), pale, coarsely haired; pilosity ca. 20–35%. Skull: braincase flat (more so than in

C. poensis and *C. nigeriae*). First upper incisor long and hooked. First unicuspid larger than second or third unicuspid. Third molar small. Nipples: not known.

Geographic Variation Specimens from Senegal are darker than those from elsewhere.

Distribution Endemic to Africa. Sudan Savanna BZ. Recorded from Jos Plateau, Nigeria (type series), and from Senegal to S Sudan (Hutterer 2005b).

Habitat In Nigeria, found in long grass, secondary bush, near to farmlands, and in rocky grasslands recently burned (Hutterer & Happold 1983). In Senegal, found in cultivated irrigated areas between series of dunes, and in swampy zones with grasses; coexists with *Dasymys rufulus* and *Mastomys huberti* (Niayes region, north of Dakar; J.-M. Duplantier unpubl.).

Abundance Locally abundant in Nigeria (Hutterer & Happold 1983).

Remarks Embryo number: 2 (n = 1: Nigeria; Happold 1987). Embryo number: 3.25 (range 2–4, n = 4; Senegal; J.-M. Duplantier unpubl.).

Predators, Parasites and Diseases Found in pellets of Barn Owls *Tyto alba* in Senegal (J.-M. Duplantier unpubl.).

Conservation IUCN Category: Least Concern.

Crocidura fulvastra SAVANNA SHREW

Fr. Crocidure de savane; Ger. Savannen-Spitzmaus

Crocidura fulvastra (Sundevall, 1843). K. Svenska Vetensk-Akad. Handl. Stockholm, 1842: 172 (publ. 1843). Bahr el Abiad, Sudan.

Taxonomy Originally described as *Sorex fulvaster*. Synonyms: *arethusa*, *beta*, *diana*, *fulvaster*, *macrodon*, *marrensis*, *sericeus*, *strauchii* (see Hutterer 1983c, 2005b, Hutterer & Happold 1983, Hutterer & Kock 1983). Subspecies: none. Chromosome number: not known.

Description Very large shrew. Dorsal pelage pale brown to cinnamon; hairs bluish-grey tipped with cinnamon. Ventral pelage and flanks whitish-grey clearly delineated from dorsal pelage; hairs grey with white tips. Tail of medium relative length (ca. 60% of HB), thin, brownish; pilosity 80–85%. Skull long and narrow in general shape, with long rostrum, narrow interorbital constriction. Braincase oval. Zygomatic process of maxilla angular. First upper incisor long and sharp, passing straight downwards. Upper premolars and molars narrow compared with *C. viaria*, *C. lamottei* and *C. butleri*. Shows considerable sexual dimorphism (Hutterer & Happold 1983). Nipples: not known.

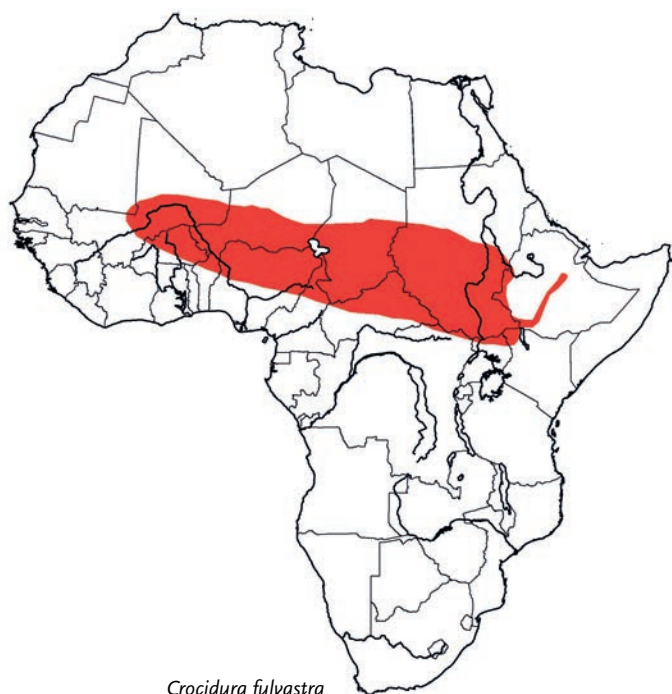

Geographic Variation None recorded.

Distribution Endemic to Africa. Sudan and Sahel Savanna BZs as well as parts of Guinea Savanna BZ in Sudan, and the Rift Valley of Ethiopia. Locality records very disjunct. Recorded from Mali, N Nigeria, S and C Sudan, Ethiopia and N Kenya. May occur in Mauritania and Senegal. One mummified specimen recorded from ancient Egypt (Hutterer 1983c).

Habitat Drier savanna habitats but likely also to inhabit a variety of mesic habitats.

Abundance Occurs quite frequently in savanna habitats in Nigeria (Hutterer & Happold 1983).

Remarks Comprised 0.3% of all shrews found in pellets of the

Spotted Eagle-owl *Bubo africanus* in Awash N. P., Ethiopia (Demeter 1982). Remains have also been found in owl pellets in Nigeria (Hutterer & Jenkins 1980, Demeter 1981). Other likely predators include small carnivores such as mongooses, genets and small cats known to feed on shrews.

Conservation IUCN Category: Least Concern.

Not uncommon and hence of no immediate conservation concern.

Crocidura fumosa SMOKY MOUNTAIN SHREW (SMOKY WHITE-TOOTHED SHREW)

Fr. Crocidure du Mont Kenya; Ger. Smoky Mountain Spitzmaus

Crocidura fumosa Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 238. Western slope of Mt Kenya. 2600 m.

Taxonomy Revised by Dippenaar & Meester (1989). Similar to *C. montis*. Synonyms: *alchemillae*. Subspecies: none. Chromosome number: not known.

Description Medium-sized shrew. Dorsal pelage dark grey-brown, slightly paler ventrally. Feet pale greyish- to yellowish-brown. Tail medium-long (50–80% of HB), greyish to reddish-brown above, paler below; pilosity 50–90%. Skull with wide interorbital region and broad high-domed braincase. Third unicuspid usually larger than second. Third upper molar moderately broad; talonid of lower third molar with entoconid and talonid basin. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. The revision by Dippenaar & Meester (1989) restricts this species to the Aberdare Range and Mt Kenya, Kenya. Also recorded from the Cherangani Hills, Kenya. Previously reported to occur widely in Kenya, Tanzania and Uganda.

Habitat Montane forest. A specimen from Mt Kenya was obtained

in a *Carex-Lobelia keniensis* bog at 12,500 ft (3800 m) (Coe & Foster 1972).

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.

Major threats are human-induced habitat loss and degradation, and restricted distribution.

Crocidura fuscumurina BICOLOURED SHREW (BICOLOURED MUSK SHREW, TINY MUSK SHREW)

Fr. Crocidure petite; Ger. Zweifarben-Spitzmaus

Crocidura fuscumurina (Heuglin, 1865). Leopoldina 5. In: Nouv. Acta Acad. Caes. Leop.-Carol. 32: 36.

Meshra-el-Req (08° 25' N, 29° 16' E), Bahr-el-hazal, Sudan.

Taxonomy Originally described as *Sorex fusco murinus*. Polytypic with several described forms. The taxonomic status of the lowveld populations in Limpopo and Mpumalanga Provinces, South Africa, requires re-examination as there is some evidence that a second species might be involved. Known as *C. bicolor* for some 50 years, but now referred to by the previously described older name of *C. fuscumurina* (Hutterer 1983b). Synonyms: *bicolor*, *bovei*, *cunninghami*, *fuscumurinus*, *?glebula*, *hendersoni*, *marita*, *sansibarica*, *tephragaster*, *tephronotus*, *woosnami*. Subspecies: none. Chromosome number: 2n = 56 (Burundi; Maddalena & Ruedi 1994).

Description Very small, predominantly grey-brown shrew grizzled with grey. Dorsal pelage grey-brown; hairs slaty-grey at base with a fawn subterminal band and brown or buffy-brown tip. Ventral pelage silvery-grey, sometimes with a yellow tinge; hairs slate-grey at base, white or off-white at tip. Dorsal and ventral colours sharply delineated. Fore- and hindfeet pale brown to off-white. Tail relatively long (ca. 65% of HB), pale to dark brown above, paler below; colours sharply demarcated; pilosity at least 75%. Western forms are paler and larger. Nipples: not known.

Geographic Variation Several forms have been described as subspecies (now listed above as synonyms). Following Heim de Balsac & Meester (1977), as *C. bicolor*, these are:

bicolor: Angola, S Zambia, S Malawi; Zimbabwe, Mozambique, Swaziland, South Africa (areas with rainfall exceeding 500 mm).

cunninghami: E Uganda, Kenya.

fuscumurina: Sudan (Bahr-el-Ghazal; holotype).

hendersoni: NE Zambia, N Malawi, Tanzania.

marita: Sudan (Jebel Marra, Darfur).

tephragaster: Sudan (Torit, Equatoria).

woosnami: N Namibia, Botswana, South Africa (Northern Cape Province).

Distribution Endemic to Africa. Widely distributed in parts of Sahel, Sudan, Guinea, Somalia–Masai and Zambezan Woodland

BZs. Recorded from many countries in West, East, east-central and southern Africa.

Habitat Woodland savannas and semi-arid regions. Recorded from grasslands, woodlands, Kalahari sand and riverine scrub habitats. Found in termite mounds, fallen logs and marshy areas. May enter domestic dwellings (Meester 1963, Smithers 1971, Lynch 1983, Monadjem 1998a, c).

Abundance Widespread but rarely collected.

Adaptations Nocturnal and terrestrial. Appears to have wide habitat tolerance and can live in mesic and moderately arid habitats.

Crocidura fuscumurina

Foraging and Food Insectivorous. Prefers moths but also eats grasshoppers, praying mantids, dragonflies and crickets in captivity (Dippenaar 1979a).

Social and Reproductive Behaviour Presumably solitary.

Reproduction and Population Structure In southern Africa, reproductive activity occurs during the wet season (Nov–Apr). Mean litter-size: 3.4 (range 2–5, $n = 8$). Weight at birth: 0.25 g to ca. 1 g. Young are born virtually hairless but after a week are fully furred. Behavioural development is rapid during the second week with the emergence of traits such as face-wiping, sniffing, scratching, yawning, jumping and the ability to climb vertically. Eyes open Day 12. Active exploration is evident from Day 17; solid food first taken Day 14–19. Initially the ♀ carries young in her mouth but this ceases when caravanning commences around Day 6. Caravanning ends just before weaning. In one litter from the Kruger National Park, caravanning was replaced by ‘back riding’, possibly an aberrant form of caravanning (Watson & Watson 1986) (see also Ansell 1964, Dippenaar 1979a).

Predators, Parasites and Diseases Remains have been found in owl pellets (Meester 1963).

Conservation IUCN Category: Least Concern.

Although uncommon, unlikely to be at risk to because of extensive geographic range and secretive habits.

Measurements

N. J. Dippenaar & R. M. Baxter

Crocidura glassi GLASS'S SHREW (ETHIOPIAN MOUNTAIN SHREW)

Fr. *Crocidure de Glass*; Ger. Äthiopien-Gebirgsspitzmaus

Crocidura glassi Heim de Balsac, 1966. Mammalia 30: 448. Gara Mulatta, Harar, Ethiopia (ca. 09° 16' N, 41° 44' E). 2700 m.

Taxonomy Considered as a well-defined species (Dippenaar 1980a, Hutterer 1980). A member of the endemic Ethiopian *C. glassi* complex (*C. glassi*, *C. lucina*, *C. thalia*, *C. macmillani* and *C. baileyi*) (Dippenaar & Meester 1989). Synonyms: none. Chromosome number: $2n = 36$ (Lavrenchenko *et al.* 1997). The level of genetic (allozyme) differentiation among populations from the Bale Mts is very high (Lavrenchenko *et al.* 1997).

Description Small-medium greyish-brown shrew. Dorsal pelage greyish-brown; hairs grey at base, brown at tip. Ventral pelage silvery-grey, hairs grey at the base, pale yellowish at tip. Dorsal surface of fore- and hindfeet pale grey. Tail relatively long (ca. 67% of HB), brown above, whitish to yellowish below; pilosity 80%. Skull with inflated braincase, as typical for the high altitude Ethiopian *Crocidura*. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ. Recorded only from Ethiopia, where confined to highlands east of the Ethiopian Rift Valley (Bale Mts, Mt Badda and Chercher Highlands), 2700–4050 m.

Habitat Upland grasslands, ericaceous scrub and afroalpine moorland, over a range of altitudes.

Abundance Numerous in suitable habitats. Comprised 18% of 229 small mammals in ericaceous scrub on the Bale Mts; the second most numerous species after *Lophuromys brevicaudus* (51%).

Crocidura glassi

Remarks Presumed to be insectivorous or omnivorous. In the Bale Mts, pregnant ♀♀ were found during the late dry season and the beginning of the wet season (late Mar–May). Embryo number: 3.13 (2–4), $n = 16$ pregnant ♀♀. Sex ratio close to unity. Contributed 15% of 92 small mammals in pellets of the Abyssinian Long-eared Owl *Asio abyssinicus* (Yalden 1973). Not eaten by Simien Wolves *Canis simensis*, presumably because distasteful (Sillero-Zubiri & Gottelli 1995).

Conservation IUCN Category: Vulnerable.

Occurs in a very restricted area, although abundant where found.

Measurements

Crociodura goliath GOLIATH SHREW

Fr. Crociodure géante; Ger. Goliath-Spitzmaus

Crociodura goliath Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 17: 177. Efulen, Cameroon.

Taxonomy Often included in *C. flavescens* or *C. olivieri*, but apparently a distinct species that lives in sympatry with *C. olivieri* in the central African rainforests (Hutterer 2005b). Synonyms: *nimbasilvanus*, *guineensis*. Subspecies: none. The names *aequatorialis* and *odorata*, which are currently listed under *olivieri*, may eventually turn out to represent *goliath*, pending the discovery of the holotypes; in that case, the species name needs to be changed. The taxa *guineensis* (preoccupied) and *nimbasilvanus* were provisionally included in *goliath* by Hutterer (2005b) but represent a distinct species endemic to West Africa (not considered in this volume). Chromosome number: $2n = 50$ (Primus *et al.* 2006).

Description Extremely large brownish-red shrew. Pelage long, sparse, slightly coarse and glossy, hairs 8–10 mm, occasionally up to 20 mm. Dorsal pelage dark rufous to chestnut-brown; hairs grey on basal half, rufous on terminal half; some individuals with long thick dark rufous hairs on back from shoulders to rump. White-tipped hairs, if present, give slight frosted appearance to pelage. Ventral pelage greyish-rufous or greyish; hairs grey at base, grey or greyish-rufous at tip. Lateral gland large and usually very obvious. Head similar to dorsal pelage. Chin, throat and chest rufous-brown. Ears relatively small. Fore- and hindlimbs dark rufous-brown; claws whitish. Tail relatively long (ca. 68% of HB), rufous-brown; pilosity 50%. Skull: large and heavily built with long CI length (see Measurements; cf. other large shrews) and robust, semi-squarish molars. In old animals, the dorsal surface of the braincase may be sculptured with inconspicuous irregular bony ripples (as seen in *Scutisorex somereni* to a much greater extent). First incisor long and hooked. Third molar narrow. Nipples: not known.

Geographic Variation Individuals from S Cameroon (Efulen), N DR Congo (Kisangani) and NE Gabon (Minkébé Forest) are larger than those at Mt Doudou, SW Gabon (Goodman & Hutterer 2004). A small coastal form may represent the taxon *odorata*, currently listed under *C. olivieri* (see Taxonomy). Mean values for four adults

at Mt Doudou are: HB: 136.8 (122–150) mm; T: 92.0 (89–96) mm; HF: 21.6 (19–23) mm; E: 14.8 (13–16 mm, WT: 48.1 (38–57) g (cf. Measurements below).

Distribution Endemic to Africa. Rainforest BZ (mainly in West Central Region, Gabon sub-region). Recorded from S Cameroon, Gabon, Equatorial Guinea (Rio Muni), N Congo, SW Central African Republic and DR Congo (north of Congo R.).

Habitat Primary rainforest (Thomas 1906a), marshes and mixed rainforest (Goodman *et al.* 2001); riparian forest and marshy forest (Nicolas *et al.* 2004).

Crociodura goliath

Abundance Varies according to habitat. In Gabon, the following abundances from short-term studies have been recorded: 8% (1 of 12 shrews, 7 spp.; marsh, Minkebe Forest), 57% (4 of 7 shrews, 4 spp.; heterogeneous rainforest, Minkebe Forest), 14% (6 of 44, 9 spp.; 110 m, Mt Doudou) and 17% (4 of 23, 6 spp.; 625 m, Mt Doudou) (Goodman *et al.* 2001; Goodman & Hutterer 2004). In a long-term study at Mt Doudou, *C. goliath* comprised 5% (25 of 503) of shrews captured in several habitats, and was the seventh most abundant species (out of nine spp.) (Nicolas *et al.* 2004).

Remarks Occurs syntopically with another very large shrew (*C. oliveri*) in Minkébé Forest, Gabon. In a study of 16s rRNA sequences, *C. goliath* clustered near *C. oliveri*, *C. flavescens*, *C. viaria* and *C. hirta* (Quéroutil *et al.* 2005). Embryo number: 3 (range not given), *n* = 5 (Mt Doudou, Gabon; Nicolas *et al.* 2004).

Conservation IUCN Category: Least Concern.

Crociodura gracilipes SHORT-FOOTED SHREW (PETERS'S MUSK SHREW)

Fr. Crocidure à pieds courts; Ger. Kleinfüßige Spitzmaus

Crociodura gracilipes Peters, 1871. Monatsber. K. Preuss. Akad. Wiss. Berlin 1870: 590 (publ. 1871).

Unidentifiable but generally accepted as Mt Kilimanjaro, Tanzania (Moreau *et al.* 1946).

Taxonomy Known only from the original specimen; possibly conspecific with *C. cyanea* (see Hutterer 1993, 2005b). Synonyms: none. Chromosome number: not known.

Description Small shrew. Dorsal pelage cinnamon-brown. Ventral pelage grey-brown; base of hairs slate-grey. Feet with sparse cinnamon-coloured hairs. Tail relatively long (ca. 80% of HB), thin, brown above, greyish-brown below, with scattered bristle hairs; pilosity not known. Nipples: not known.

Crociodura gracilipes

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Distribution uncertain but type locality usually accepted as Mt Kilimanjaro, Tanzania. Reports of *C. gracilipes* occurring more widely in eastern and western Africa cannot be confirmed because many specimens have been wrongly attributed.

Habitat No information.

Abundance Known only from the holotype.

Remarks No information.

Conservation IUCN Category: Data Deficient.

Distribution extremely restricted.

***Crocidura grandiceps* LARGE-HEADED SHREW**

Fr. Crocidure à grande tête; Ger. Großköpfige Spitzmaus

Crocidura grandiceps Hutterer, 1983. Rev. Suisse Zool. 90: 699. Krokosua Hills, N of Asempanaya (Asampaniye), Sedfwi Wiaso, Ghana.

Taxonomy Genetically allied to the *turba-poensis* complex (Quérrouil *et al.* 2005). Some of the specimens reported as *C. poensis* (Happold 1977) belong to this species. Synonyms: none. Chromosome number: $2n = 46$, $FN = 68$ (Schlitter *et al.* 1999).

Description Very large brown shrew, similar to (and difficult to distinguish from) *C. nigeriae*. Dorsal pelage clove-brown. Ventral pelage similar to dorsal pelage, but paler. Fore- and hindfeet dark brown. Tail medium-long (ca. 55–65% of HB), slightly bicoloured, brown above, paler below; pilosity not known. Skull large (when compared with species of similar size, e.g. *C. longipes*, *C. nigeriae*); slightly domed. Upper incisor long, almost straight. First unicuspid pointed, larger than second and third unicuspid; second and third unicuspid equal; all three with cingulum. Third upper molar medium to large. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (Western Region and parts of West Central Region). Recorded from Guinea, Côte d'Ivoire, Ghana, W Nigeria, and possibly Cameroon (not mapped).

Habitat Primary and degraded rainforest.

Abundance Uncertain because of problems with identification. Probably an uncommon species. The following percentages (of shrews captured) were obtained in Taï N. P. (Côte d'Ivoire): 0.5% ($n = 390$, 9 spp.) in forest and 2.1% ($n = 140$) in cocoa-coffee plantations (Barrière *et al.* 1999). In Ziam Biosphere Reserve (Guinea), percentage abundances were 1.6% ($n = 509$, 10 spp.) in secondary forest, 1.6% ($n = 484$, 9 spp.) in old fallow land, 1.2% ($n = 303$, 10 spp.) in young forest plantations and 0.8% ($n = 500$, 11 spp.) in primary forest. This species was not captured in fields ($n = 272$, 9 spp.) nor in old forest plantations (441 shrews, 9 spp.) (P. Barrière, unpubl.).

Remarks Probably similar to *C. nigeriae* and *C. poensis*. See Happold (1987) and Hutterer & Happold (1983) for further details.

*Crocidura grandiceps*

Conservation IUCN Category: Near Threatened.

Measurements*Crocidura grandiceps*HB: 117 (98–119) mm, $n = 19$ T: 65 (55–74) mm, $n = 19$ HF: 18.1 (17–19) mm, $n = 19$ E: 11 (10–12) mm, $n = 18$ WT: 23.5 (19–27) g, $n = 18$ CI: 26.1 (25.4–27.4) mm, $n = 15$ GWS: 10.9 (10.6–11.7) mm, $n = 12$ I^1-M^3 : 11.4 (10.6–11.7) mm, $n = 17$

***Crocidura grassei* GRASSÉ'S SHREW**

Fr. Crocidure de Grassé; Ger. Grasses Spitzmaus

Crocidura grassei Brosset, Dubost and Heim de Balsac, 1965. Biologia Gabonica 1: 165. Belinga, Gabon.

Taxonomy Related to the *maurisca-littoralis* group (Quérrouil *et al.* 2005). Synonyms: none. Chromosome number: $2n = 40$ (Primus *et al.* 2006).

Description Medium-sized grey shrew, the largest of the *dolichura*-group. Pelage soft and dense; hairs 2–3 mm. Dorsal pelage greyish-brown; hairs grey at base, greyish-brown at tip.

Ventral pelage greyish-beige, paler than dorsal pelage; hairs grey at base, beige at tip. Head similar colour to dorsal pelage. Fore- and hindfeet not pigmented, sparsely covered with short white hairs. Tail relatively very long (ca. 95% of HB), bicoloured, medium to dark brown above, whitish below; long white hairs on tail; pilosity ca. 15%. Braincase slightly domed. First upper incisor long, hooked. Unicuspid pointed; first unicuspid larger than second and third; second and third subequal; all three with well developed cingulum. Third upper molar medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (Gabon sub-region). Recorded from Gabon, Central African Republic, S Cameroon and Equatorial Guinea (Rio Muni). Perhaps occurs in N Congo.

Habitat Rainforest, especially riparian habitats and marshes (Nicolas *et al.* 2004).

Abundance Considered as rare (Nicoll & Rathbun 1990, Goodman *et al.* 2001), but may be locally quite common. Frequency of occurrence in various regions includes 9% (one of 11; 7 spp.) in a marsh in Minkébé Forest, NE Gabon (Goodman *et al.* 2001), 10% (8 of 72; 9 spp.) at Mt Doudou (Goodman & Hutterer 2004) and 9% (46 of 503; 9 spp.) at Mt Doudou (Nicolas *et al.* 2004).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Crocidura greenwoodi GREENWOOD'S SHREW

Fr. Crocidure de Greenwood; Ger. Greenwoods Spitzmaus

Crocidura greenwoodi Heim de Balsac, 1966. Monitore Zool. Ital. 74 (Suppl.): 215. Gelib, Somalia.

Taxonomy Related to *C. fulvastra* and *C. hirta* (Hutterer 1993, 2005b), with which it shares the same karyotype (Schlitter *et al.* 1999). Synonyms: none. Chromosome number: 2n = 50, FN = 66 (Schlitter *et al.* 1999).

Description Small–medium shrew. Dorsal pelage grey tinged with brown. Ventral pelage whitish, hairs grey at base. Feet greyish. Tail relatively long (ca. 72% of HB), thick; pilosity 75%. Braincase broad and flattened. Second and third unicuspid subequal in size. Third upper molar medium. Talonid of third lower molar with a talonid basin and entoconid small or absent. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded only from S Somalia.

Habitat Gallery forest, savanna, bush and arid regions; cultivated land.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Major threats are human-induced habitat loss and degradation, and restricted distribution.

Crocidura greenwoodi

Crocidura harena HARENNA SHREW

Fr. Crocidure de Harena; Ger. Harena Spitzmaus

Crocidura harena Hutterer and Yalden, 1990. In: Vertebrates in the Tropics (eds G. Peters and R. Hutterer), Bonn. p. 64. Katchja clearing, Harena Forest, Bale, Ethiopia.

Taxonomy One of the nine endemic species of Ethiopian shrews (Hutterer & Yalden 1990, Hutterer 2005b). Specimens referred to as *Crocidura* sp. A by Yalden (1988a) became the type series for this species. May be related to *C. phaera*, which is known only from Sidamo, Ethiopia. Synonyms: none. Chromosome number: 2n = 36, FN = 50 (Lavrenchenko *et al.* 1997).

Description Small–medium grey shrew. Pelage soft and dense; hairs 4.5 mm on back. Dorsal and ventral pelage dark slate-grey, without any trace of brown colour. Snout, ears, fore- and hindlimbs also slate-grey. Tail relatively long (ca. 66% of HB), with numerous long bristle hairs (<6 mm); pilosity ca. 80% (cf. sympatric *C. bottegoides*: 0%). Skull high-domed; braincase almost hexagonal in dorsal view. First upper incisor moderately long and hooked. First upper unicuspid large, second and third unicuspid about half height of first unicuspid. Third upper molar relatively large. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the type locality (Harena forest; 06°42'N, 39°44'E) in the Bale Mts of Ethiopia at 2400 m where it co-exists with the smaller *C. bottegoides* (Yalden 1988a).

Habitat *Schefflera*–*Hagenia* montane forest; this contrasts with *C. bottegoides*, which is a grassland species in the same area.

Crocidura harena

Abundance Rare. Known from six specimens (type series) out of 100 shrews (5 spp.) trapped in all habitats in Bale N. P. in 1971–1986 (Yalden 1988a), and the only species in the *Schefflera*–*Hagenia* montane forest. Also eight specimens (of 82 shrews) trapped in 1995 from various sites in Bale N. P. (Lavrenchenko *et al.* 1997).

Remarks One pregnant ♀♀ (WT: 11.5 g) and two sexually active ♂♂, recorded in Aug (D.W.Yalden unpubl.); no data for other months.

Conservation IUCN Category: Critically Endangered.

The limited distribution of the species, and the threat of habitat destruction, are cause for concern.

Measurements

Crocidura harena

Crocidura hildegardeae HILDEGARDE'S SHREW

Fr. Crocidure de Hildegarde; Ger. Hildegardes Spitzmaus

Crocidura hildegardeae Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 240. Fort Hall, Kenya.

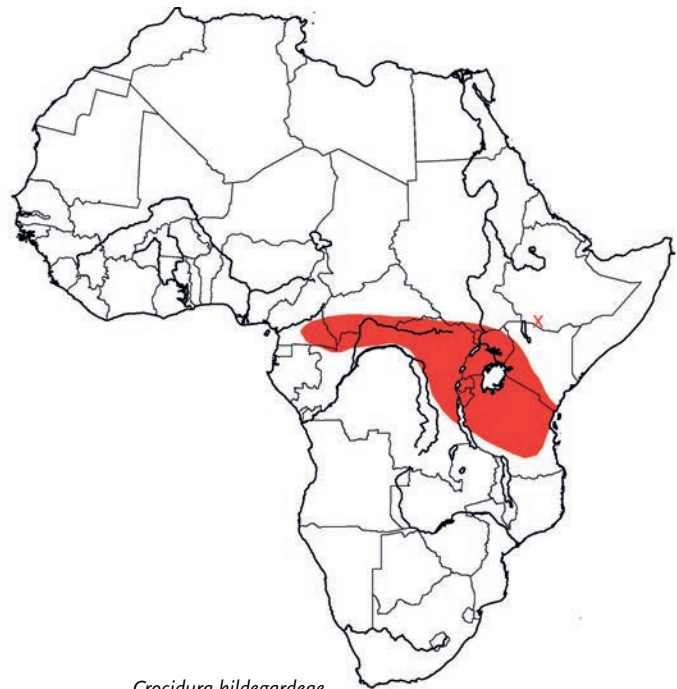

Taxonomy Considered a subspecies of *C. gracilipes* by Heim de Balsac & Meester (1977) but a valid species by Dieterlen & Heim de Balsac (1979), Demeter & Hutterer (1986) and Hutterer (1993, 2005b). Synonyms: *altae*, *holobrunneus*, *ibeana*, *lutreola*, *maanjan*, *phaios*, *procera*, *rubecula*. Hutterer (2005b) lists *virgata* (from Cameroon), previously listed as a synonym of this species, as a valid species on the grounds that it has a different chromosome number ($2n = 52$, $FN = 86$; Schlitter *et al.* 1999) to *C. hildegardeae*. Subspecies: none. Chromosome number: $2n = 52$, $FN = 76$ (Burundi; Maddalena & Ruedi 1994). Taxonomic revision of this species is required.

Description Small-medium shrew with prominent ears. Hairs 3.5 mm on rump, 3 mm on neck and back, 2.4 mm on ventral surface. Dorsal pelage milk-chocolate-brown; dorsal hairs chocolate-brown, dark brown at tip. Ventral pelage pale brown. Forelimbs chocolate-brown, hindlimbs dark brown on outer side, yellowish-brown on inner side. Tail relatively long (ca. 70% of HB), subtly bicoloured, black above, brown below; pilosity ca. 35%. Males usually larger than ♀♀ (Stanley *et al.* 1996a). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Gabon sub-region] and East Central Region), Northern and Eastern Rainforest–Savanna Mosaics, and Afromontane–Afroalpine BZ of eastern and central Africa. Recorded from SE Cameroon and Congo to Kenya and Tanzania. In Tanzania, known from Mt Meru, the South Pare, East and West Usambara and the Udzungwa Mts (Dieterlen & Heim de Balsac 1979, Demeter & Hutterer 1986, Hutterer 1993, Stanley *et al.* 1996a, 1998). Limits of distribution uncertain.

Habitat Dry forest and wetter forests of montane and highland areas in eastern Africa. Found in both undisturbed and moderately disturbed sub-montane forests of East Usambara Mts. More common at mid-elevation dry forests than at higher elevation wetter montane forests of South Pare and Udzungwa Mts (Stanley *et al.* 1996a, W.T. Stanley unpubl.). In Rwanda, known from cultivated areas and moist savannas (Hutterer *et al.* 1987).

Crocidura hildegardeae

Abundance Varies by habitat and elevation. In Tanzania, the most abundant shrew at 1100 m (78% of total sample; n = 37), but the least abundant (30% of total sample; n = 10) at 2000 m in the South Pare Mts (Stanley *et al.* 1996a).

Remarks Terrestrial and nocturnal. Pregnancy rates were 25% (n = 12; Jul; South Pare Mts, Tanzania) and 50% (n = 6; Aug; East Usambara Mts). Embryo number: 2 (n = 3; East Usambara Mts). In Aug (1993), 64% of sample were juveniles (East Usambara Mts; Stanley *et al.* 1996, W.T. Stanley unpubl.). ♂ : ♀ ratio was 1 : 1 (South Pare Mts, 1100 m) and 1 : 3 (East Usambara Mts). Remains found in small carnivore scats in the Central African Republic (Ray & Hutterer 1995), and in the stomach of a sedge viper (*Atheris nitschei*) (Allen & Loveridge 1942).

Conservation IUCN Category: Least Concern.

William T. Stanley

Crocidura hirta LESSER RED SHREW (LESSER RED MUSK SHREW)

Fr. Crocidure petite rousse; Ger. Kleine Moschusspitzmaus

Crocidura hirta Peters, 1852. Reise nach Mossambique, Zool. 1, Säugetiere: 78, pl. 18, fig. 2. Tete, Zambezia, Mozambique (17S).

Taxonomy Polytypic. Synonyms: *annellata*, *beirae*, *bloyeti*, *canescens*, *deserti*, *flavidula*, *langi*, *luimbalensis*, *velutina* (see Heim de Balsac & Meester 1977). The two southern African forms are relatively well delimited. Subspecies: none (see also below). Chromosome number: 2n = 50 (Maddalena & Ruedi 1994).

Description Medium-sized shrew. Dorsal pelage cinnamon-brown, grizzled with reddish-fawn to dark-brown; hairs slaty-grey at base, with fawn subterminal band and brown or buffy-brown tip. Ventral pelage paler with yellow to fawn tinge; hairs grey at base with yellow to fawn tip. Dorsal colour can be sharply delineated from central colour. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet fawn. Tail of medium to very long relative length (ca. 55% of HB in South Africa, up to 90% in central Africa) (Ansell & Dowsett 1988), brown above, pale grey below; pilosity up to 100%. Nipples: 0 + 3 = 6.

Geographic Variation Heim de Balsac & Meester (1977) recognized four forms as subspecies (here listed as synonyms):

deserti: W and S Angola, Zambia, NE Namibia, NE South Africa, Botswana. Dorsal pelage creamish-brown.

hirta: Zambia, SE Tanzania, Zimbabwe, N South Africa, Mozambique, Swaziland.

langi: DR Congo.

velutina: N Tanzania.

Distribution Endemic to Africa. Primarily Zambezan Woodland BZ and southern part of Somalia–Masai Bushland BZ. Recorded from SE Angola, SE DR Congo, Tanzania, Malawi, Zimbabwe, Zambia, Mozambique, Botswana, Swaziland, NW Namibia and N South Africa. Perhaps occurs in Kenya and Somalia. Limits of distribution uncertain.

Habitat Montane forest, bushveld, savanna and woodlands; requires some cover such as piles of debris, fallen logs or urban compost heaps (Smithers & Wilson 1979). Often commensal with humans, as is the Greater Musk Shrew (*Crocidura flavescens*) and African Giant Shrew (*C. olivieri*). Very wide habitat tolerance.

Abundance Uncertain, but common in urban gardens in Pretoria (South Africa), Bulawayo and Harare (Zimbabwe) as well as in suitable habitats throughout its range.

Adaptations Appears to be similar to the Greater Musk Shrew *Crocidura flavescens* but is less aggressive.

Foraging and Food Largely insectivorous, but will also prey on vertebrate prey (Meester 1960) as well as molluscs.

Social and Reproductive Behaviour Predominantly nocturnal with greatest peak of activity at dusk with a secondary peak at dawn (Baxter *et al.* 1979); thus there is temporal separation between this species and *C. flavescens* in their zone of sympatry. Vocalizations include a short, loud squeak when encountering a strange conspecific or when alarmed.

Scent marking using lateral glands has been observed. Faecal piles are strongly scented, suggesting some form of territoriality. Grooming behaviour includes scratching with the hindfeet and face-washing. Rectum licking has been observed (Baxter & Meester 1980).

Mating behaviour includes ‘flehmen’, when the male sniffs the ano-genital region of a female (Baxter 1981), and chasing. Copulation is

Crocidura hirta

brief after a chase of seven minutes. As in *C. flavescens*, the ♂ may be dragged along by his penis before disengagement. Nests are usually saucer-shaped (Baxter & Meester 1980) and are often situated at the end of a long tunnel underneath a rock (Meester 1960).

Reproduction and Population Structure In South Africa, pregnancies recorded during wet season and early dry season (Sep–May), but mostly in Jan–Feb. Gestation: ca. 28 days. Litter-size: 4.1 (2–5), mode 4, $n = 8$ (R. M. Baxter unpubl.). In (former) Transvaal, South Africa, breeding occurs from Nov–May and mean litter-size is 3.8 ($n = 7$) (Rautenbach 1982); in Zimbabwe, breeding is recorded in Sep, Dec and Feb, and mean litter-size is 3.6 ($n = 5$) (Smithers & Wilson 1979). At birth, HB = 31 mm, T = 8.1 mm, HF = 5.1 mm, E = 2.5 mm and weight = ca. 1 g ($n = 29$). Young are born naked, blind and helpless but development is rapid. When the young start to walk on Day 9, caravanning can be observed. Eyes and ears open around Day 12. Full pelage is present by Day 14, and caravanning ceases after Day 18. Weaning occurs at ca. Day 18. A postpartum oestrus is present and consecutive litters may be produced (Meester 1963, R. M. Baxter unpubl.).

Predators, Parasites and Diseases Known predators include African Grass-owls *Tyto capensis* and Barn Owls *Tyto alba*, as well as

Black-necked Cobras *Naja nigricollis*. As with *C. flavescens*, domestic cats kill but do not eat this shrew.

Conservation IUCN Category: Least Concern.

A relatively common shrew in urban gardens throughout its range.

Crocidura jacksoni JACKSON'S SHREW

Fr. Crocidure de Jackson; Ger. Jacksons Spitzmaus

Crocidura jacksoni Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 238. Ravine Station, Kenya.

Taxonomy Synonyms: *amalae* (see Heim de Balsac & Meester 1977). Subspecies: none. Chromosome number: not known.

Description Small–medium shrew with soft, smooth short pelage. Dorsal pelage fawn to dark brown; hairs grey at base, brown at tip. Flanks similar to dorsal pelage. Ventral pelage whitish-grey; ventral hairs dark grey, whitish-grey at tip. Chin and throat similar to ventral colour. Head narrow with long-pointed muzzle with long dark brown vibrissae and very small eyes. Ears small, oval and dark brown; held laterally and backwards from head. Fore- and hindlimbs short and slender, with sparse short pale brown hairs. Tail thin and relatively long (ca. 75% of HB); buff above and on sides, grey below; small dark scales, pilosity at least 66%. Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ, Eastern Rainforest–Savanna Mosaic and some parts of Afromontane–Afroalpine BZ in eastern Africa. Recorded from Uganda, Kenya, N Tanzania and E DR Congo.

Habitat Forests, wet bushlands and cultivated areas where annual rainfall is more than 1000 mm. In East Africa, inhabits moist forests in highland regions from 1400 m. In the eastern Rift Valley of Kenya, has been captured in cultivated areas (C. O. Odhiambo & N. O. Ouge, unpubl.) at elevations of over 1800 m.

Abundance Common in the Taita Hills, Kenya, where widely distributed in forest fragments. Collected in 11 of 14 forest fragments, comprising 13% of all shrews captured; the second most abundant species of shrew (after *C. hildegardeae*) (Ouge *et al.* 2004).

Crocidura jacksoni

Remarks Diet includes a wide range of invertebrates, including ants, beetles and termites. Preyed on by Barn Owls *Tyto alba* (skull recovered from pellets collected in Rongai Division, Kenya). Ectoparasites have not been recovered from this species.

Conservation IUCN Category: Least Concern.

Reduction in size and extent of forest fragments has probably reduced the geographic range of the species in recent years. Its presence in farming lands may suggest adaptability to environmental disturbance.

Crocidura jouvenetae JOUVENET'S SHREW

Fr. Crocidure de Jouvenet; Ger. Jouvenet Spitzmaus

Crocidura jouvenetae Heim de Balsac, 1958. Mém. Inst. Fr. Afr. Noire 53: 331. Ziéla, Mt Nimba, Guinea.

Taxonomy Referred to as a subspecies of *C. crossei* by Hutterer (1993) and Grubb *et al.* (1998). However, *jouvenetae* and *ebriensis* (described as a subspecies of *C. jouvenetae* by Heim de Balsac & Aellen 1958) are larger animals and represent a separate species (Hutterer 2005b). The form *ebriensis* was listed as a species by Maddalena & Ruedi (1994) and Schlitter *et al.* (1999). Synonyms: *ebriensis*. Subspecies: none. Chromosome number: 2n = 44, FN = 66.72 (Maddalena & Ruedi 1994, as *C. ebriensis*).

Description Small-medium greyish-brown shrew. Pelage short and dense. Dorsal pelage greyish-brown. Ventral pelage paler without any clear delineation with colour of flanks. Head long, similar in colour to dorsal pelage, paler under chin. Upper part of face dark grey to black; lower part silvery, delineated clearly from upper face. Ears large and well developed. Fore- and hindfeet pale or flesh-coloured. Tail relatively long (ca. 66% of HB), thick (especially at base; diameter 5–6 mm), bicoloured; pilosity ca. 75%. Nipples: not known.

Geographic Variation Specimens from forests at Mt Nimba are smaller and darker than those elsewhere (Heim de Balsac 1968a).

Distribution Endemic to Africa. Rainforest BZ (Western Region). Recorded from S Guinea, Liberia and S Côte d'Ivoire (Hutterer 2005b). May also occur in Sierra Leone (Grubb *et al.* [1998], as *C. crossei jouvenetae*).

Habitat Primary and secondary lowland forest and cocoa-coffee plantations within the forest. Specimens also caught in moist rainforest near coastal lagoons, and near savanna (Dabou, Côte d'Ivoire). At Mt Nimba, found in forested habitats at the base of the mountains (Heim de Balsac 1958).

Abundance Common in all localities where it has been captured. In Taï N.P., Côte d'Ivoire, common in secondary forest (18.5%, n = 390 shrews, 9 spp.) and in cocoa-coffee plantations (16.5%, n = 140 shrews, 7 spp.) (Barrière *et al.* 1999). In Ziama Biosphere Reserve, Guinea, common in young forest plantations, primary forest, old fallow land and secondary forest (25.1%, n = 303 shrews, 10 spp.; 22.4%, n = 500, 11 spp.; 18.2%, n = 484, 9 spp.; and 15.7%, n = 509, 10 spp., respectively), but less common in fields (14.7%, n = 272, 9 spp.) and in old forest plantations (10.9%, n = 441, 9 spp.) (P. Barrière, unpubl.). At Adiopoudome, Côte d'Ivoire, more abundant than syntopic *C. poensis* (Heim de Balsac & Aellen 1958).

Crocidura jouvenetae

Remarks The commonest prey items (% frequency of occurrence) in 26 stomachs in Taï N.P., Côte d'Ivoire, were representatives of the following taxa: Formicidae (80.8%), Araneae (42.3%), Diplopoda (26.9%), Coleoptera adults (23.1%), Blattodea (11.5%), Gryllidae (7.7%), Lepidoptera larvae (3.8%), Mantidae (3.8%), Diptera adults (3.8%) and Isopoda (3.8%). This analysis suggests that *C. jouvenetae* is a specialist feeder on ants. (Churchfield *et al.* 2004).

Conservation IUCN Category: Least Concern.

Crocidura kivuana KIVU SHREW

Fr. Crocidure de Kivu; Ger. Kivu-Spitzmaus

Crocidura kivuana Heim de Balsac, 1968. Biologia Gabonica 4: 319. Tshibati, Kivu, DR Congo.

Taxonomy Belongs to the *monax* species-group, a complex of 12 related species occurring in high montane areas of Cameroon, central and East Africa, four of which (*C. kivuana*, *C. lanosa*, *C. littoralis* and *C. stenocephala*) are endemics of the Albertine Rift Valley (Hutterer 1986b). Resembles *C. maurisca* and *C. congobelgica* (Heim de Balsac 1968c, Heim de Balsac & Meester 1977). Synonyms: none. Chromosome number: not known.

Description Small–medium shrew with a relatively long tail. Dorsal pelage blackish with a distinct brownish tinge, especially on the head; hairs silvery ash-grey at base, blackish with brownish tinge at tip. Ventral pelage ashy-grey without brownish tinge, paler than dorsal pelage; hairs silvery ash-grey at base, grey with brownish tinge at tip. Ears naked, usually not covered by pelage. Hindfeet brownish, short-haired; forefeet paler. Tail relatively very long (ca. 89% of HB), not tapering towards tip, blackish brown above, slightly paler below; pilosity 0–20%; some specimens have slight pencil at tip. Skull: cranium domed, with broad maxillary width. Upper third unicuspid larger than upper second unicuspid (cf. *C. maurisca* and *C. congobelgica* in which the third upper unicuspid is smaller than the second). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa Afromontane–Afroalpine BZ flanking the Albertine Rift Valley. Confined to a small montane region west of L. Kivu between Lwiro (1700 m) and the peak of Mt Kahuzi (3300 m). Probably widely distributed in undisturbed areas above 2000 m.

Habitat At lower altitudes, swamps with *Cladium mariscus* and *Cyperus latifolius* are the preferred habitat. At higher altitudes, recorded from swamps with *Cyperus latifolius*, primary and secondary mixed montane forests, and (rarely) bamboo forest. One individual was obtained in the afroalpine vegetation on the top of Mt Kahuzi at 3300 m (Dieterlen & Heim de Balsac 1979).

Abundance Abundant in some swampy habitats, representing ca. 50% of captured shrews. Often syntopic with *C. stenocephala* in some swampy habitats on Mt Kahuzi, E DR Congo.

Remarks Four ♀♀ were pregnant during the wet season (Oct, Nov, Mar). Embryo number: 1.67 (1–2), n = 3.

Conservation IUCN Category: Vulnerable.

Threatened because of its rarity and very restricted geographic and ecological range; adequate conservation of this species is similar to that of the other endemic species of the Albertine Rift Valley region.

Crocidura lamottei LAMOTTE'S SHREW

Fr. Crocidure de Lamotte; Ger. Lamottes Spitzmaus

Crocidura lamottei Heim de Balsac, 1968. Mammalia 32: 386. Lamto, Côte d'Ivoire.

Taxonomy Synonyms: *elegans*. Subspecies: none. Chromosome number: 2n = 52, FN = 68 (Meylan 1971).

Description Medium-sized shrew with relatively pale-coloured pelage. Dorsal pelage pale brown to grey-brown, without flecking; hairs bluish-grey, brown at tip. Ventral pelage grey or silvery-grey washed with yellowish tint; hairs medium grey at base, creamy-grey at tip. Vibrissae long. Ears conspicuous, not concealed by pelage; appear naked but covered with short hairs. Hindfoot relatively short. Fore- and hindlimbs flesh-coloured covered with short pale brown hairs. Tail medium length (ca. 53% of HB), thick, broad at base narrowing towards tip; flesh-coloured with reddish blotches; pilosity 100%. Skull similar to *C. butleri* but larger. First incisor long and hooked. Third molar narrow. Mandible very robust, particularly the coronoid process. Nipples: not known.

Geographic Variation Specimens from the north of the range are paler dorsally and pure grey ventrally compared with specimens from the south, and have slightly larger skull measurements providing possible justification of a subspecies (? *C. l. elegans*) (Hutterer 1986a, Hutterer & Schlitter 1996).

Distribution Endemic to Africa. Sudan and Guinea Savanna BZs of West Africa. Recorded from Senegal to W Cameroon, including Nigeria, Côte d'Ivoire, Liberia, Senegal and possibly Togo (Heim de Balsac & Meester 1977, Hutterer 1981b, Hutterer & Happold 1983). Specimens from Owerri, S Nigeria recorded as *C. foxi* (Hutterer & Happold 1983) are in fact *C. lamottei* (Hutterer 2005b). One record from the Rainforest BZ (Korup N. P., Cameroon; Hutterer & Schlitter 1996).

Habitat Recorded from a variety of habitats; found primarily in dry forest, grasslands in savanna, amongst dry grasses on rocky hillside, and in grassy clearings (Heim de Balsac 1968a, Hutterer & Happold 1983, Hutterer 1986a, Hutterer & Schlitter 1996, Decher *et al.* 1997).

Abundance No information.

Remarks Found inhabiting termitaria (Heim de Balsac 1968a). One pregnant ♀ bearing a single embryo was found at the beginning of the dry season in Ghana (Decher *et al.* 1997).

Conservation IUCN Category: Least Concern.

P. D. Jenkins & S. Churchfield

Crocidura lanosa KIVU LONG-HAIRED SHREWFr. *Crocidura laineuse* de Kivu; Ger. Kivu-Langhaarspitzmaus*Crocidura lanosa* Heim de Balsac, 1968. Biologia Gabonica 4: 309. Lemera. Kivu Province, DR Congo.

Taxonomy Belongs to the *monax* species-group, a complex of 12 related species occurring in high montane areas of Cameroon, central and East Africa, four of which (*C. kivuana*, *C. lanosa*, *C. littoralis* and *C. stenocephala*) are endemic to the Albertine Rift Valley (Hutterer 1986b). Synonyms: none. Chromosome number: not known.

Description Large shrew (the largest of the *monax*-group). Pelage long and dense, woolly with dull texture. Dorsal pelage almost unicoloured blackish-grey with a superficial brownish tinge; hairs with white tip. Ventral pelage blackish-grey, but slightly paler than dorsal pelage, possibly with a brownish tinge. Eyes small. Ears medium-sized, partly covered by pelage. Fore- and hindfeet brownish. Hindfoot relatively long. Tail relatively long (ca. 80% of HB), dark, covered with short dark bristles except at terminal end; pilosity ca. 33%. (Some specimens have whitish hairs at tip of tail, forming a small pencil.) Skull elongated; maxillary and cranial regions broad; cutting edge of lower incisor normally smooth, rarely with a denticle. Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from montane forests on the slopes of the Albertine Rift Valley of E DR Congo and Rwanda (Rugege Forest, now Nyungwe Forest) on both east and west sides of L. Kivu at 1800–2500 m (Heim de Balsac 1968b, Dieterlen & Heim de Balsac 1979, Hutterer *et al.* 1987).

Habitat Primarily montane forest including thick undergrowth and glens (n = 24), and mixed forests (primary and secondary) with bamboo (n = 9). Not recorded from open habitats nor from montane swamps.

Abundance Comprised 15% of shrews (33 of 222; 10 spp.) caught in all montane habitats (1800–3300 m) W of L. Kivu, DR Congo, and 23% of shrews in habitats where the species was present (Dieterlen & Heim de Balsac 1979).

Remarks Dense woolly pelage is possibly an adaptation to cold temperatures and wet conditions in the mountains. Pregnant ♀♀ found during the wet season (Oct, Nov, Jan) but not at other times of the year. Embryo number: 2 (n = 2), 6 (n = 1). Sex ratio of captured shrews: ca. 2 : 1.

*Crocidura lanosa*

Conservation IUCN Category: Endangered.

This species is threatened because of its rarity and very restricted geographic and ecological range; in this respect it is similar to the other endemic species of the Albertine Rift Valley region.

Measurements*Crocidura lanosa*

HB: 95.6 (87–105) mm, n = 33

Crocidura latona LATONA'S SHREW

Fr. Crocidence de Latona; Ger. Latonas Spitzmaus

Crocidura latona Hollister, 1916. Bull. Amer. Mus. Nat. Hist. 35: 667. Medje, NE DR Congo.

Taxonomy Similar to *C. niobe* in size, but *C. latona* is distinguishable by its uniform dark brownish colouration on upper and lower parts. Skull and teeth very similar to *C. maurisca* and *C. littoralis*, but smaller. May be related to the paler-coloured *C. jacksoni*, which is similar in size and also possesses a fovea on M₃. Brosset *et al.* (1965b) suggested that *C. ludia* may be a synonym, but this seems unlikely since it has a smaller skull and a longer more sparsely haired tail than *C. latona*. Synonyms: none. Chromosome number: not known.

Description Small-medium, lightly built dark-coloured shrew. Dorsal pelage rich dark-brown. Ventral pelage slightly paler brown than on back and sides. Lateral flank glands russet. Fore- and hindfeet buffy-brown, very thinly haired. Tail relatively very long (ca. 85% of HB), blackish-brown, very slightly paler below at base; pilosity ca. 20%. Skull small. Unicuspid rather narrow with small cusps and large cingula; second and third unicuspid relatively wide and inclined to be circular. Last upper premolar is longer than wide. A fovea is present on the talonid of M₃. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ of NE DR Congo. Known only from four localities: near Medje, near Kisangani (Masako Forest Reserve), Okapi Faunal Reserve (Katuala *et al.* 2005) and Irangi.

Habitat Lowland primary and secondary rainforest. Captured in secondary forest, along creek-sides and in fallow land in Masako Forest, near Kisangani (Dudu *et al.* 2005).

Abundance Appears to have small, highly localized populations and is rarely found in trapped samples. Comprised 7% of shrews (5 of 72; 9 spp.) during three years of trapping in Masako Forest, DR Congo (Dudu *et al.* 2005).

Adaptations Ground-dwelling species. Feeds on a wide range of invertebrates, primarily arthropods. Stomach analyses (n = 5) showed that major prey comprised Formicidae and Diptera (each 17% by composition), Isoptera, Coleoptera, Acrididae, Araneae and Diplopoda (each 10–12%). Invertebrate prey ranged in body length from 3 mm to 30 mm with 80% being <10 mm (Dudu *et al.* 2005).

Conservation IUCN Category: Least Concern.

Previously assessed as Vulnerable (B1 + 2c). Major threats are habitat modification, particularly deforestation, and the restricted geographic range.

Crocidura littoralis NAKED-TAILED SHREW

Fr. Crocidure des rives; Ger. Nacktschwanz-Spitzmaus

Crocidura littoralis Heller, 1910. *Smithson. Misc. Coll.* 56 (15): 5. Butiabi, east shore of L. Albert, Uganda.

Taxonomy Formerly included in *C. monax*, but now considered a distinct species (Dieterlen & Heim de Balsac 1979, Hutterer 1993). The subspecies *C. l. stenocephala* (see Dieterlen & Heim de Balsac 1979) is now regarded as a valid species. The specimens referred to *C. maurisca* from Kenya (Hollister 1918) are probably *C. littoralis* (Dieterlen & Heim de Balsac 1979). Synonyms: *oritis*. Subspecies: none. Chromosome number: not known.

Description Large shrew. Dorsal pelage blackish or dark brown; hairs ash-grey at base, brownish at tip. Ventral pelage (including undersurface of head and neck) similar to dorsal pelage or greyish-brown; hairs silvery-grey at base, brownish-grey at tip. Ears darkly pigmented, with very short dark hairs on outer edge. Hindfeet dark brown, forefeet medium-brown. Tail relatively long (ca. 73% of HB), blackish above, slightly paler below; appears naked, with a few longer bristles at base of tail (pilosity ca. <25%). Skull similar to that of *C. stenocephala*, but clearly broader; cutting edge of mandibular incisors with (two) inconspicuous denticles. Nipples: not known.

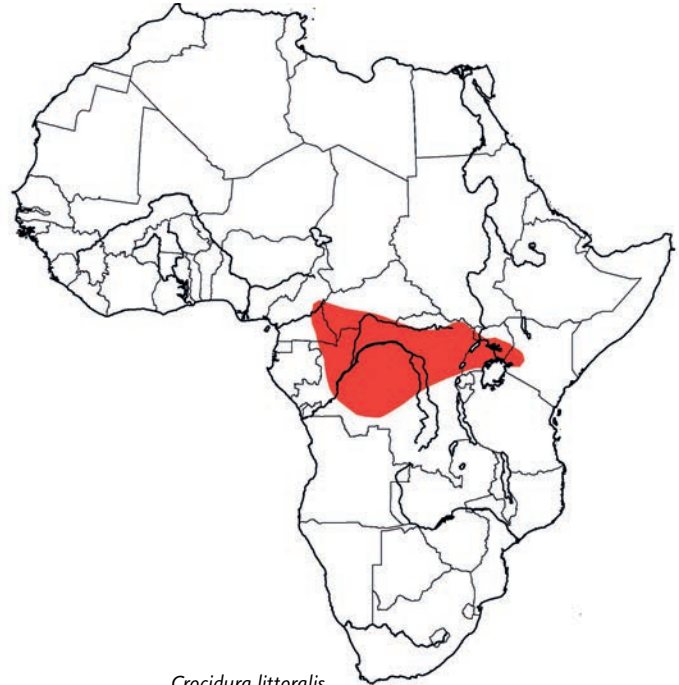

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (West Central [Gabon sub-region], South Central and East Central Regions) and Eastern Rainforest–Savanna Mosaic. Recorded from a few localities in SW Central African Republic, Cameroon, Congo, DR Congo, Uganda and Kenya (Dieterlen & Heim de Balsac 1979, Hutterer 1993, Ray & Hutterer 1995).

Habitat Closed-canopy rainforest. Appears unevenly distributed on both a local and regional basis (Dieterlen & Heim de Balsac 1979).

Abundance Usually rare, but can be locally abundant (Dieterlen & Heim de Balsac 1979).

Remarks In Masako Forest, E DR Congo, one of the rarest shrews, comprising ca. 1% (1 of 72) of the shrew community (equal eighth commonest species; 9 spp.) (Dudu *et al.* 2005). Diet includes species of Formicidae, Diptera and Lepidoptera larvae, Heteroptera, Isoptera and Araneae (n = 1; Dudu *et al.* 2005). Litter-size: 2–4 (n = 2; Kivu, DR Congo) (Dieterlen & Heim de Balsac 1979). Found in 2.3% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995, Ray 1998).

*Crocidura littoralis*

***Crocidura longipes* LONG-FOOTED SHREW (SAVANNA SWAMP SHREW)**

Fr. Crocidure à longs pieds (Crocidure des marais); Ger. Savannen-Sumpfspitzmaus

Crocidura longipes Hutterer and Happold, 1983. Bonn. Zool. Monogr. 18: 53. Dada, Nigeria.**Taxonomy** Synonyms: none. Chromosome number: not known.**Description** Very large chocolate-brown shrew with long hindfeet. Dorsal pelage and ventral pelage uniformly dark brown. Fore- and hindfeet dark brown. Hindfeet comparatively long (ca. 17% of HB). Tail of medium relative length (ca. 60% of HB), brown; pilosity unknown ('sparsely haired'). Skull long and pointed; interorbital and maxillary regions narrow; dentition weak, especially upper molars. Nipples: not known.**Geographic Variation** None recorded.**Distribution** Endemic to Africa. Guinea Savanna BZ. Recorded from only two localities in Nigeria – Dada and Iella (2 miles E of Bahindi).**Habitat** Swampy areas with tall grasses (1–2 m in height), palm trees and scattered other trees. May occur in other swamps along major river systems in Guinea Savanna BZ. Syntopic with *Crocidura olivieri* in one swamp (C. B. Robbins in Hutterer & Happold 1983).**Abundance** Unknown. Known only from seven specimens.**Remarks** Apparently no other information available.**Conservation** IUCN Category: Data Deficient.

Nigeria (Hutterer & Happold 1983)

Key Reference Hutterer & Happold 1983.**D. C. D. Happold*****Crocidura lucina* LUCINA'S SHREW**

Fr. Crocidure de Lucina; Ger. Lucinas Spitzmaus

Crocidura lucina Dippenaar, 1980. Ann. Transvaal Mus. 32: 134. Web River, near Dinshu, Bale, Ethiopia (ca. 07°06' N, 39°46' E). 3000 m.**Taxonomy** Specimens recorded as *C. baileyi* by Osgood (1936) and Yalden *et al.* (1976) are now allocated to this species (Dippenaar & Meester 1989). A member of the endemic Ethiopian *C. glassi* complex (*C. glassi*, *C. lucina*, *C. thalia*, *C. macmillani* and *C. baileyi*) (Dippenaar & Meester 1989). Synonyms: none. Chromosome number: 2n = 36 (Lavrenchenko *et al.* 1997).**Description** Medium-sized shrew, with a distinctly bicoloured pelage and tail. Pelage long and soft. Dorsal pelage greyish-brown to reddish-brown; hairs grey at base, rufous at tip. Ventral pelage greyish-white, hairs grey at the base, white at tip. Dorsal surface of fore- and hindfeet whitish. Tail relatively short (ca. 62% of HB), brown above, whitish below; pilosity 100%. Skull with inflated braincase, as typical for the high altitude Ethiopian *Crocidura*. Nipples: not known.**Geographic Variation** None recorded.**Distribution** Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only in the highlands east of the Ethiopian Rift Valley (Bale Mts and Mt Badda), Ethiopia, 3000–4050 m.

Habitat Afroalpine moorland, and grasslands at lower altitudes (Yalden 1988, Lavrenchenko *et al.* 1997).

Abundance Rare. Comprised 1.9% ($n = 535$) of small mammals caught in the Bale Mts (Yalden 1988a, b).

Remarks Woolly fur and relatively short tail might be adaptations to the cold at high altitudes. One pregnant ♀ (with two embryos) trapped in the Bale Mts in the late dry season (early Mar; L. Lavrenchenko unpubl.). Seems to be avoided as prey by Simien Wolves *Canis simensis* (Sillero-Zubiri & Gottelli 1995).

Conservation IUCN Category: Least Concern.

Distribution very limited. Protected within the proposed Bale Mountains N. P.

Crocidura ludia LUDIA'S SHREW

Fr. Crocidure de Ludia; Ger. Ludias Spitzmaus

Crocidura ludia Hollister, 1916. Bull. Amer. Mus. Nat. Hist. 35: 668. Medje, DR Congo.

Taxonomy Included in *C. dolichura* by Heim de Balsac & Meester (1977), but reinstated as a full species by Hutterer & Dippenaar (1987a). The species may include more than one species (Quérrouil *et al.* 2005). Synonyms: none. Chromosome number: not known.

Description Small brown shrew. Dorsal pelage uniformly brown; hair grey at base, brown at tip. Ventral pelage brown, rather similar to dorsal pelage. Fore- and hindfeet buff, thinly haired, with brown streak along outside. Tail relatively very long (84–87% of HB), blackish-brown above, paler on basal third below; appears naked but covered with short dark bristles; long hairs restricted to base of tail (pilosity 20–30%). Skull (depicted in Hollister 1916, pl. 7, fig. 4) small and gracile, similar to *C. dolichura* in general configuration. Braincase rounded, rostrum slender; skull tapering from the interorbital region to the tip of the skull; braincase strongly inflated in lateral view. Dentition weak; upper first incisor short and small; M³ large. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ and Northern Rainforest–Savanna Mosaic. Recorded from DR Congo (Medje, Tandala, Masako forest near Kisangani, Yoko forest south of Kisangani; Hollister 1916, Hutterer & Dippenaar 1987, Dudu *et al.*

2005, Mukinzi *et al.* 2006) and Central African Republic (Dzanga-Sangha F.R., Batouri, Bohou; Ray & Hutterer 1995, Barrière *et al.* 2005).

Habitat In Masako Forest, found only in secondary forest (not in primary forest, along creeks, or in fallow land) (Dudu *et al.* 2005). In Bohou (Central African Republic), found in gallery forest and moist savanna habitats (Barrière *et al.* 2005).

Abundance Rarely collected. In Masako Forest, comprised ca. 3% (2 of 72, 9 spp.) of shrews captured (Dudu *et al.* 2005). In Bohou (Central African Republic) surprisingly constituted the dominant species, with 71% (41 of 58, 7 spp.) of shrews captured (Barrière *et al.* 2005).

Remarks Stomach contents ($n = 2$) include representatives of the following: adult Coleoptera, Formicidae, Lepidoptera larvae, Blattodea, Diplopoda, Araneae and seeds (Dudu *et al.* 2005). Occasionally recorded (1.3% of 311 shrews; 16 spp.) in scats of carnivores from Central African Republic; one of the predators was *Herpestes naso* (Ray & Hutterer 1995). Three other similar species are potentially sympatric with *C. ludia*: *C. polia*, *C. dolichura* and *C. latona*.

Conservation IUCN Category: Least Concern.

Crocidura ludia

Crocidura luna MOONSHINE SHREW (GREY-BROWN MUSK SHREW)

Fr. Crocidure sélène; Ger. Grosse graubraune Moschusspitzmaus

Crocidura luna Dollman, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 175. Bunkeya River, Katanga, Shaba Province, DR Congo.

Taxonomy A member of the *luna-fumosa* complex (Dippenaar & Meester 1989). Synonyms: *electa*, *garambae*, *inyangai*, *johnston*, *schistacea*, *umbrosa*. Subspecies: none. Chromosome number: 2n = 36 (Maddalena & Ruedi 1994).

Description Medium-sized shrew. Dorsal pelage brownish-grey to very dark brownish-grey; hairs slaty-grey at base, pale fawn or grey subterminal band and paler or darker at tip. Ventral pelage slightly to obviously paler and greyer; hairs slaty-grey at base, pale fawn to olive at tip. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet usually pale brownish-grey to yellowish-brown or brown. Tail relatively long (ca. 61% of HB), dark brown to blackish-brown above, paler below. Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezian Woodland BZ, extending into southern part of Somalia–Masai Bushland BZ and Eastern Rainforest–Savanna Mosaic. Recorded from extreme NE DR Congo, Uganda, Kenya, most of Tanzania, Zambia, SE DR Congo, WC Mozambique and Malawi; outlier population in Inyanga Highlands of Zimbabwe and adjacent Mozambique (Dippenaar & Meester 1989).

Habitat Moist, cool areas, typically on the fringes of montane forest where there is dense cover, in matted grass along streams where rainfall exceeds 1000 mm (Smithers & Lobão Tello 1976,

Smithers & Wilson 1979), on hillsides with tussock grass (Skinner & Smithers 1990), and in *Pinus* plantations (Happold & Happold 1987). Recorded up to 1400 m on Mt Kilimanjaro (Grimshaw *et al.* 1995), and at 1900 m on Zomba Plateau (Malawi) (Happold & Happold 1989a).

Crocidura luna

Abundance Uncertain, but mostly rarely encountered. Three individuals captured in Afromontane grasslands on Zomba Plateau during monthly sampling (10 months); the only species of shrew recorded in this habitat. Recorded in most plantations of *Pinus patula* (ages 1–32 years) where abundant grass cover is present (Happold & Happold 1987).

Remarks Nocturnal, with peaks of activity at dawn and dusk; terrestrial (Smithers & Wilson 1979). Reproductive activity has been reported in Oct and Nov when 3–4 young are born (Smithers & Wilson 1979).

Conservation IUCN Category: Least Concern.

Measurements

Crocidura lusitania MAURITANIAN SHREW

Fr. Crocidure de Mauritanie; Ger. Mauritanien-Spitzmaus

Crocidura lusitania Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8., 15: 516. Trarza country, Mauritania.

Taxonomy Synonyms: none. Chromosome number: 2n = 38, aFN = 70 (Oursi, Burkina; Maddalena & Ruedi 1994).

Description Very small to small shrew. Dorsal pelage cinnamon-brown with very short hairs. Ventral pelage pure white (Nigeria) to greyish. Head grey. Lips, chin and throat white. Fore- and hindfeet white. Hindfeet short. Tail of medium relative length (ca. 56% of HB), bicoloured, ashy-grey above, white below; pilosity 100%. Skull very flat and very small. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sudan and Sahel Savanna BZs of West Africa and southern part of Mediterranean Coastal BZ. Recorded from Morocco, Mauritania, Senegal, Côte d'Ivoire, Burkina, Niger and N Nigeria. Two isolated records from Eritrea and Ethiopia (Aulagnier & Thévenot 1986, Happold 1987, Ag Sidiyène 1989, Hutterer 1993, Maddalena & Ruedi 1994).

Habitat Tree and bush savannas and traditionally cultivated fields in Senegal. Also present in sandy areas and coastal dunes along the Senegalese and Mauritanian coasts (Granjon *et al.* 1997, J.-M. Duplantier unpubl.). In Senegal, syntopic with *C. cinderella*, *C. fuscomurina*, *C. lamottei* and *C. olivieri* at Mbour, and probably with *C. viaria* and *C. lamottei* in *Acacia* bush savanna at Ferlo (J.-M. Duplantier unpubl.). Sometimes occupies termite mounds.

Abundance Can be locally abundant. Comprised nearly 50% of shrews trapped at Mbour, Senegal, between Sep and Dec 1988 (J.-M. Duplantier unpubl.). Comprised 50% of all prey in pellets of Barn Owls *Tyto alba* in Fètè-Olè, Senegal (Poulet 1982), and one-third of all shrews found in pellets of Barn Owls in the Senegal delta (Bâ *et al.* 2000).

Remarks Apparently no other information available.

Crocidura macarthuri **MACARTHUR'S SHREW**

Fr. Crocidure de MacArthur; Ger. MacArthurs Spitzmaus

Crocidura macarthuri St Leger, 1934. Ann. Mag. Nat. Hist., ser. 10, 13: 559. Merifano, 32 km from mouth of Tana River, Kenya.

Taxonomy Recorded from Somalia as *smithi* (e.g. Heim de Balsac 1966; see Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Medium-sized shrew very similar to, but smaller than, *C. fischeri*. Dorsal pelage bluish-grey with brownish tinge. Ventral pelage white; hairs grey on basal half, white on terminal half. Upper lips, throat, behind ears, fore- and hindfeet white; hairs grey on basal half, white on terminal half. In some specimens, white hairs are washed with buff or grey. Tail of medium relative length (56% of HB), white, thick at base, tapering towards tip; pilosity not known. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded in widely dispersed localities from S Kenya (Nguruman) to central Somalia (Belet Amin).

Habitat Wooded grassland with widely scattered tree species, e.g. *Acacia tortilis*, interspersed with *Themeda*, *Hyparrhenia* and *Cenchrus* grasses (S Kenya). These habitats are generally hot and daytime temperatures may reach 40 °C, and are marginal for agriculture.

Abundance Very rare. No quantitative information.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Should perhaps be classified as Data Deficient.

Crocidura macmillani **MACMILLAN'S SHREW**

Fr. Crocidure de Macmillan; Ger. Macmillans Spitzmaus

Crocidura macmillani Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 514. Koteke, Walamo, Ethiopia (ca. 06° 45' N, 37° 53' E). 1900 m.

Taxonomy Considered as a well-defined species of the endemic Ethiopian *glassi* complex (*C. glassi*, *C. lucina*, *C. thalia*, *C. macmillani* and *C. baileyi*) (Dippenaar 1980a, Dippenaar & Meester 1989). Although previously considered to be phylogenetically distant from

this endemic Ethiopian group (Bannikova *et al.* 2001), molecular phylogenetic analysis (Inter-SINE-PCR) supports the validity of the species (Bannikova *et al.* 2005). Formerly included in *C. fumosa* (Yalden *et al.* 1976) or *C. luna* (Heim de Balsac & Meester 1977,

Hutterer 1980). Synonyms: none. Chromosome number: $2n = 28$ (L. Lavrenchenko unpubl.).

Description Small-medium dark shrew with narrow skull. Dorsal pelage dark brownish-grey to blackish-grey; hairs grey at base, black at tip. Ventral pelage dark grey; hairs uniformly grey to dark grey. Upper surface of fore- and hindfeet dark grey. Tail relatively long (ca. 70% of HB), blackish-grey above, grey below; pilosity 75%. Skull narrow with inflated braincase as typical for the endemic Ethiopian *Crocidura*. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from Koteke (06° 45' N, 37° 53' E), the Middle Godjeb Valley (07° 15' N, 36° 47' E) and Sheko Forest (07° 04' N, 35° 30' E) in Ethiopia.

Habitat Humid afromontane forests; humid woodland *Terminalia*–*Combretum* savanna with high grass.

Abundance Rare; known only from four specimens (L. Lavrenchenko & R. Hutterer unpubl.). Comprised 2.5% of 79 small mammals trapped in the Middle Godjeb Valley (L. Lavrenchenko unpubl.).

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.
Distribution very limited.

Crocidura macowi NYIRO SHREW

Fr. Crocidure du Mont Nyiro; Ger. Nyiro-Spitzmaus

Crocidura macowi Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 378. Mt Nyiro, S of L. Rudolf [L. Turkana], Kenya.

Taxonomy Regarded as a synonym of *C. hildegardae* by Osgood (1936), but retained as a species by Heim de Balsac & Meester (1977), who noticed similarities to *C. niobe* (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Small shrew. Dorsal pelage dark brown. Ventral pelage greyish-brown or slate-grey. Fore- and hindfeet dark brown. Tail relatively long (ca. 80% of HB); pilosity ca. 55%. Third unicuspid larger than second; third upper molar medium in size, talonid of third lower molar with entoconid and talonid basin. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from the type locality, Mt Nyiro, south of L. Rudolf (L. Turkana), Kenya.

Habitat No information.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Previously considered as Critically Endangered. Major threats are human-induced habitat loss and degradation, and very restricted distribution.

Crocidura macowi

Crocidura manengubae MANENGUBA SHREW

Fr. Crocidure des Monts Manengouba; Ger. Manenguba-Spitzmaus

Crocidura manengubae Hutterer, 1982. Bonn. Zool. Beitr. 32: 242. Lager III, L. Manenguba, Bamenda Highlands, Cameroon. 1800 m.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Medium-sized brown shrew without any long hairs on tail. Pelage soft and dense; hairs 5–6 mm. Dorsal pelage medium-brown tinged russet; hairs grey on basal two-thirds, russet-brown on terminal third. Ventral pelage brownish-grey, contrasting slightly with dorsal pelage; hairs grey at base with pale brown, grey or beige at tip. Fore- and hindfeet dark russet-brown. Tail relatively long (ca. 75% of HB), very dark blackish-brown; pilosity 0%. First incisor long and hooked. Third incisor medium to wide. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the Bamenda and Adamaoua highlands, Cameroon. Unconfirmed report from highlands near Yaounde, Cameroon (see Heim de Balsac 1968d).

Habitat Swamp on the shoreline of L. Manenguba (an extinct crater lake), and in grass and shrub habitats close to the edge of the lake. The forested regions on the steeply sloping sides of the crater lake are also the only known habitat of *Praomys hartwigi*.

Abundance Very rare; known only by the holotype and paratype, and from remains in owl pellets.

Remarks Recorded from owl pellets in the Adamaoua highlands, Cameroon, near the border with Nigeria (Hutterer & Joger 1982).

Conservation IUCN Category: Vulnerable.

Key Reference Hutterer 1982.**Rainer Hutterer*****Crocidura maquassiensis* MAKWASSIE SHREW**

Fr. Crocidure de Maquassie; Ger. Makwassie-Moschusspitzmaus

Crocidura maquassiensis Roberts, 1946. Ann. Transvaal Mus. 20: 312. Klipkuil, Makwassie, Wolmaransstad district, North West Province, South Africa.**Taxonomy** Might be a southern form of *C. suaveolens* (Pallas, 1811) – a Palaearctic species – and may be closely related to *C. pitmani* (Meester *et al.* 1986). Synonyms: *malani*. Subspecies: none. Chromosome number: not known.**Description** Very small to small shrew. Dorsal pelage grey-brown washed with grey; hairs slaty-grey with a fawn subterminal annulation and brown tip. Ventral pelage grey tinged with fawn; hairs slaty-grey with pale grey tip. Colours of dorsal and ventral pelage merge on flanks. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet pale brown. Tail relatively long (ca. 71% of HB), dark brown above, paler below; pilosity ca. 70%. Nipples: 0 + 3 = 6.**Geographic Variation** None recorded.**Distribution** Endemic to Africa. Southern part of Zambezan Woodland BZ. Distribution disjunct, generally restricted to rocky or montane habitats above 1500 m (two specimens known from coastal northern KwaZulu–Natal, South Africa). Recorded from Zimbabwe (Nyamaziwa Falls, Inyanga; Matopo Hills), Swaziland (Mantenga Falls), South Africa (North West, Limpopo, Gauteng, Mpumalanga and KwaZulu–Natal Provinces).**Habitat** Montane vegetation or rocky areas (Meester 1963); but P. Taylor (1998) suggests a broader habitat preference.**Abundance** Rare. Although known from Swaziland, not recorded during recent extensive mammal surveys (A. Monadjem unpubl.).**Remarks** One pregnant ♀ collected in Oct contained three embryos (Skinner & Smithers 1990).**Conservation** IUCN Category: Least Concern.**Measurements***Crocidura maquassiensis*

Crocidura mariquensis SWAMP SHREW

Fr. Crocidure des marais; Ger. Sumpf-Moschusspitzmaus

Crocidura mariquensis (A. Smith, 1844). Illustr. Zool. S. Afr. Mamm. pl. 44, fig. 1. 'A wooded ravine near the Tropic of Capricorn'
(= Marico River near its junction with Limpopo River, North West Province, South Africa).

Taxonomy Originally described in the genus *Sorex*. Synonyms: *neavei*, *pilosa*, *shortridgei*, *sylvia*. Subspecies: three. Chromosome number: not known.

Description Small-medium to medium-sized shrew. Dorsal pelage blackish-brown grizzled lightly with reddish-fawn; hairs slaty-grey at base, with reddish-fawn to reddish-brown subterminal bands and blackish-brown tip. Ventral pelage paler; dark brown grizzled with fawn; hairs slaty-grey at base, fawn to pale brown at tip. Colours of dorsal and ventral pelage merge on flanks. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet yellowish-brown, brown or blackish-brown. Tail relatively long (ca. 70% of HB), brown, reddish-brown to blackish-brown above, sometimes paler below; pilosity 26–53% (see below). There is distinct geographical variation and sexual dimorphism in size (see below; also Dippenaar 1977, 1979b). Nipples: 0 + 3 = 6.

Geographic Variation

C. m. mariquensis: South Africa, Swaziland, S Mozambique. Dark subspecies; pilosity 51%.

C. m. neavei: SC Angola; SE DR Congo, Zambia. Dark subspecies; smaller than *C. m. mariquensis*; pilosity ca. 26%.

C. m. shortridgei: NE Namibia, Botswana (Okavango Delta, along the Chobe R. and south to Maun), extreme NW Zimbabwe. Pale subspecies; pilosity 35%.

Distribution Endemic to Africa. Zambezan Woodland BZ, parts of Highveld BZ and marginally into the Coastal Forest Mosaic BZ (in South Africa). Distribution disjunct. Restricted to marshes and inundated grasslands in three distinct regions: (a) C Angola, SE DR Congo, and W and C Zambia; (b) NE Namibia, N Botswana and extreme NW Zimbabwe; (c) N and NE South Africa, Swaziland and S Mozambique (Dippenaar 1977, Heim de Balsac & Meester 1977, Ansell 1978, Monadjem 1998a, c).

Habitat Riverine and semi-aquatic vegetation and reed-beds; only found in close proximity to open water, with a distinct preference for marshy conditions (Dippenaar 1977). Very strict habitat requirements.

Abundance Relatively common in suitable habitats. On the Kafue Flats, Zambia, populations highest in the wet season and early dry season; comprised 37% (57 of 153) of all species of shrews (4 spp.) captured during one year, and was the commonest species of shrew (*C. hirta* 35%, *C. occidentalis* 27%) (Sheppe 1973).

Adaptations The digits of hindfeet are conspicuously splayed when walking and this may be an adaptation to marshy habitats (Baxter & Meester 1980). In Zambia (Kafue Flats), during the wet season (Jan–Jul), 40% of individuals ($n = 48$) contained fat reserves whereas none ($n = 8$) contained fat in dry season (Aug–Dec; Sheppe 1973).

*Crocidura mariquensis*

Foraging and Food Feeds on snails and termites in captivity (Baxter & Meester 1980).

Social and Reproductive Behaviour Predominantly nocturnal (Baxter *et al.* 1979), although some authors record diurnal activity as well (e.g. Rautenbach 1982). When moving, the tail may uniquely be curved slightly upwards (Baxter & Meester 1980). This species is particularly active and agile (compared with other species) and shows little or no animosity towards conspecifics (Goulden & Meester 1978, Baxter & Meester 1980). Vocalizations include short, sharp squeaks and short 'chirrs' during aggressive encounters. Scent-marking has not been observed, although both the body of the shrew and the faecal piles are strongly scented. Digging and rooting behaviour are virtually absent. Nests are not actively built in captivity but an individual will creep into nesting material where, by moving about, it makes a hollow (Baxter & Meester 1980). One instance of a spherical nest is known (Meester 1963). In the field, nests have been found deep in clumps of tussock grass and in debris about 30 cm above ground.

Reproduction and Population Structure In South Africa, reproductive activity in the subspecies *mariquensis* has been recorded during the wet season (Sep–Feb); litter-size: 4.1 (2–7), $n = 18$ (Taylor, P. 1998, R. M. Baxter unpubl.). In Botswana, reproductive activity in the subspecies *shortridgei* occurs during the wetter warmer months of the year (Aug–Apr); embryo number: 3.3 (range 2–5), $n = 22$ (Smithers 1971). In Zambia (Kafue Flats), three pregnant

♀ ♀ found in Aug, and one each in Sep and Oct (Flats flooded); and one each in Feb and Apr (wet season); embryo number: 3.8 (range 2–5), $n = 6$ (Sheppe 1972, 1973).

Predators, Parasites and Diseases Preyed on by Fiscal Shrikes *Lanius collaris* (Meester 1963), Barn Owls *Tyto alba* and African Grass-owls *Tyto capensis* (Vernon 1972).

Conservation IUCN Category: Least Concern.
Destruction of wetlands could threaten this species.

Crocidura maurisca GRACILE NAKED-TAILED SHREW (DARK SHREW)

Fr. Crocidure maure; Ger. Grazile Nacktschwanzspitzmaus

Crocidura maurisca Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 239. Entebbe, Uganda.

Taxonomy The 23 specimens from Kaimosi, Kenya, named as *maurisca* (Hollister 1918) are now considered to represent *C. littoralis* (Dieterlen & Heim de Balsac 1979). Belongs to the *C. maurisca*–*littoralis* species-group (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Medium-sized greyish-black shrew. Dorsal hairs long (7–8 mm). Dorsal pelage black. Ventral pelage grey. Upper surface of fore- and hindfeet black (as dorsal pelage). Hindfeet relatively long (20% of HB). Tail relatively very long (ca. 89% of HB), with dense short hairs; pilosity: 10–15%. Skull with long rostrum, narrow maxillary width (5.75–6.2 mm), elongate maxillary unicusps with small cusps and large cingula. Males are mostly larger than ♀ ♀ (see Measurements). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Eastern Rainforest–Savanna Mosaic. Only recorded with certainty from six localities, mostly high elevation swamps in Uganda (Echuya, Mubwindi, Ngoto), and Burundi, and one record from Gitebe (near Rutshuru), E DR Congo (Dieterlen & Heim de Balsac 1979). A single record of an unsexed, young specimen from Gabon (Goodman *et al.* 2001) at 600 m is far removed from the main distribution of the species and needs verification. The species has not been collected at the type locality (Entebbe) since described (see above) and it is possible that it was not collected there. Specimens from Kaimosi, Kenya (Hollister 1918) are probably *C. littoralis* (Dieterlen & Heim de Balsac 1979).

Habitat Prefers montane sedge swamps of the Albertine Rift Valley (1500–2400 m). In Kibira National Park (Burundi, 2180 m),

Crocidura maurisca

and Echuya and Mubwindi Swamps (Uganda, 2380 and 2070 m), the typical habitat is sedge swamp with water-loving herbs, bracken and shrubs (*Hypericum* sp., *Rubus* sp. and *Brillantasia cicatricosa*). A single record comes from Ngoto Swamp (a papyrus swamp, 1500 m), while another came from the edge of shallow stream adjacent to the sedge habitat in Burundi.

Abundance Although exceedingly rare, may be relatively common in its restricted favoured habitats; comprised 15% of captured small mammals in Echuya Swamp and was one of the most common species (28%) within a sedge meadow in the Gitenge Valley, Kibira N. P., Burundi.

Remarks Although mostly nocturnal (84%, $n = 18$), some individuals were collected during the day. The relatively long hindfeet may be an adaptation to the swampy environment. Stomach contents have yielded remains from the following invertebrate groups: Orthoptera, Homoptera, Araneida and Diptera (FMNH). Trapping results in more ♂♂ (8 of 9 specimens in Burundi, and 6 of 8 specimens in Uganda) than ♀♀. Information on reproduction not available.

Conservation IUCN Category: Least Concern.

Measurements

Crocidura monax KILIMANJARO SHREW (ROMBO SHREW)

Fr. Crocidure du Mont Kilimanjaro (Crocidure de Rombo); Ger. Kilimanjaro-Spitzmaus

Crocidura monax Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 6: 310. Rombo, Mt Kilimanjaro, Tanzania. 6000 ft (1829 m).

Taxonomy Considered to be distinguishable from *C. littoralis*, but part of the *monax*–*littoralis* species-complex (Dieterlen & Heim de Balsac 1979, Hutterer 1993). Heim de Balsac & Meester (1977) considered *ultima* to be a subspecies of *C. monax*, but Hutterer (1993) recognized *C. ultima* as a distinct species. Burgess *et al.* (2000a) considered that *monax* was endemic to Mt Kilimanjaro, while Stanley *et al.* (1998a) listed it from a number of mountains in N Tanzania. Synonyms: none. Chromosome number: not known.

Description Small–medium shrew with rich brown pelage. Hairs 6 mm on back, 5.5 mm on shoulders, 4.5 mm on ventral surface. Dorsal pelage rich brown; hairs steel-grey at base, brown at tip. Ventral pelage similar in colour to dorsal pelage; hairs pale brown at tip. Ears visible but not prominent. Fore- and hindlimbs slightly paler than dorsal pelage. Claws on forefeet 1.9 mm; on hindfeet 2.4 mm. Tail relatively long (70% of HB), very dark above, paler below; pilosity ca. 50%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Montane habitats of W Kenya (Amala R.) and Tanzania. Recorded from Amala R. in W Kenya, Mt Kilimanjaro, and some of the Eastern Arc Mountains in Tanzania, including the West Usambara and Uluguru Mountains (Allen & Loveridge 1927, Aggundey & Schlitter 1986, Hutterer 1993, Stanley *et al.* 1998a).

Habitat Moist undisturbed montane forest. Not observed in disturbed forests or agricultural areas at the same elevation.

Crocidura monax

Abundance The most numerous species in undisturbed forest in the West Usambara Mts, comprising 77% of shrews sampled ($n = 26$) (W.T. Stanley unpubl.).

Remarks No juveniles of this species were recorded while sampling shrews in the West Usambara Mts in Jul–Sep 1991–1993. Within the same sample, the ♂ : ♀ ratio was 17 : 5 ($n = 22$). No

pregnant ♀♀ were recorded, and ♂♂ had testes lengths of 3–6 mm and widths of 2–4 mm (W.T. Stanley unpubl.).

Conservation IUCN Category: Least Concern.

Probably Vulnerable because of fragmented distribution and decline in suitable habitat.

Crociodura montis MONTANE SHREW (MONTANE WHITE-TOOTHED SHREW)

Fr. Crocidure de montagne d'Afrique; Ger. Hochland-Weißzahnschneckenmaus

Crociodura montis Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 138. Rwenzori East, Uganda. 12,000 ft (= Bujongolo, Mubuku Valley, E slope of Mt Rwenzori, Uganda; see Dippenaar & Meester 1989).

Taxonomy Formerly included in *C. fumosa* but separated by Dippenaar & Meester (1989). Synonyms: none. Chromosome number: not known.

Description Small-medium, very dark shrew. Pelage soft and dense; hairs ca. 4 mm. Dorsal pelage and ventral pelage very dark brown to blackish-brown; hairs dark grey on basal half, dark brown with slight russet tinge on terminal half. Head similar in colour to dorsal pelage. Ears small, partially concealed by pelage. Fore- and hindfeet pale golden-brown to brown. Tail relatively long (ca. 72% of HB), dark blackish-brown; pilosity 60–70% (mean 70%, range 51–89%, n = 75; Dippenaar & Meester 1989). Skull compact. Rostrum short, interorbital region wide, braincase rounded in dorsal and inflated in lateral view. Infraorbital bridge wide. First incisor long and hooked; third molar wide. Molariform teeth wide and contrasting with the row of small unicuspid. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of eastern Africa. Recorded from Mt Kilimanjaro, Ngorongoro Crater and Mt Meru (Tanzania), Mt Rwenzori and Mt Elgon (Uganda), Imatong Mts (S Sudan) and Cherangani Hills and Mt Kenya (Kenya). Also occurs in a few other isolated montane habitats (details in Dippenaar & Meester 1989). Distribution disjunct. The record of this species in Bwindi Impenetrable N. P., Uganda, is in error (J. Kerbis, *in litt.*).

Habitat Montane forests on Mt Meru (Demeter & Hutterer 1986). On Mt Elgon, Uganda (Clausnitzer *et al.* 2003), was recorded from a variety of habitats at 3200–4120 m including *Erica* forest (3460 m), grassland/*Erica* forest (3200 m), montane grassland (3870 m), *Alchemilla* shrub (3850 m), and in bogs in montane grasslands (3590 and 4120 m); it occurred in both dry and wet boggy sites, although dry sites (85% of 93 captures) were preferred; not recorded in montane forest (cf. Mt Meru).

Abundance In preferred habitats on Mt Elgon (montane grasslands, *Erica* forest and *Alchemilla* shrub), *C. montis* comprised 59% (n = 131) of the two insectivorous small mammals (i.e. *Lophuromys flacopunctatus* and this species) (Clausnitzer *et al.* 2003). On Mt Meru, Tanzania, it was the commonest (79%) of two species of shrews on the escarpment at 'Meru East' (1550–2750 m) (*C. montis*: 26 of 33; cf. *C. allex*: 7 of 33; Demeter & Hutterer 1986).

Remarks Sympatric with *C. allex* on Mt Kilimanjaro and Mt Meru. The only species of shrew at higher altitudes on Mt Elgon. May be confused with *C. fumosa* in other parts of East Africa. Generalist, opportunistic insectivore. Primarily insectivorous, with lesser amounts of other invertebrates. On Mt Elgon, Uganda, feeds on 20 groups of invertebrates; the commonest food items

Crociodura montis

(as assessed by frequency of occurrence in stomach contents, in order of frequency) were Araneae, adult Coleoptera, Lepidoptera larvae and earthworms. Less frequently eaten foods were Coleoptera larvae, adult Diptera, Heteroptera and Diplopoda, as well as small amounts of other invertebrates. Seeds and plant leaves/stems occurred in 35–42% of stomachs (% frequency of occurrence; $n = 40$ stomachs; Clausnitzer *et al.* 2003). This species and *Lophuromys flavopunctatus* are the only insectivorous small mammals at the higher elevations of Mt Elgon. The dietary overlap of the two species is 36%; *C. montis* eat fewer Diptera larvae and earthworms, and more adult Coleoptera and Araneae, than *L. flavopunctatus*. Both species consumed seeds to a similar extent (ca. 7% dietary occurrence), but *C. montis* ate far less vegetable material (ca. 6% dietary occurrence) than *L. flavopunctatus* (ca. 27% dietary occurrence) (Clausnitzer *et al.* 2003).

Conservation IUCN Category: Least Concern.

Rainer Hutterer

Crocidura muricauda WEST AFRICAN LONG-TAILED SHREW (MOUSE-TAILED SHREW)

Fr. Crocidure à queue de souris; Ger. Westafrikanische Langschwanzspitzmaus

Crocidura muricauda (Miller, 1900). Proc. Wash. Acad. Sci. 2: 645. Mount Coffee, Liberia.

Taxonomy Originally described in the genus *Myosorex*. Formerly included as a subspecies in *C. dolichura* but differs from this species by the hairiness of tail (cf. no long hairs on tail of *C. dolichura*) (Hutterer & Happold 1983). Genetically not closely related to *C. dolichura* (Quérrouil *et al.* 2005). May include different morphological forms, perhaps representing sibling species (Quérrouil *et al.* 2005). Synonyms: none. Chromosome number: not known.

Description Small shrew with large ears and long tail. Pelage soft; hairs ca. 3 mm. Dorsal pelage greyish-brown; hairs grey at base, brown at tip. Ventral pelage whitish-grey; hairs grey at base, white at tip. Head similar in colour to dorsal pelage. Ears large in relation to head, more or less naked. Fore- and hindfeet flesh-coloured, sparsely covered with short white hairs. Tail pale brown, extremely long (120–150% of HB), not bicoloured; tail hairs tend to be short and less visible than in other *Crocidura*; pilosity varies from 50 to 80%. Skull long and narrow, braincase round in dorsal view and inflated in lateral view. Rostrum slender. First incisor small. Upper dentition weak, third molar large (Miller 1900, Heim de Balsac & Aellen 1958). Nipples: not known.

Geographic Variation High variability of tail length, pilosity and genetic distances suggest that more than one species is included in *C. muricauda* (Quérrouil *et al.* 2005).

Distribution Endemic to Africa. Rainforest BZ (Western Region). Recorded from Sierra Leone, Liberia, SE Guinea, Côte d'Ivoire and W Ghana.

Habitat Rainforest and secondary forest. Sibling forms also found in degraded forest, including plantations and fields.

Abundance Locally common. Comprised 21.5% of all shrews captured ($n = 553$) in Tã N. P. with pit traps, and the second

Throughout geographic range (except Mt Elgon) (Dippenaar & Meester 1989)

Key References Clausnitzer *et al.* 2003; Dippenaar & Meester 1989.

most numerous species of shrew ($n = 10$ spp.) (Churchfield *et al.* 2004). Rare in cocoa–coffee plantations in Tã N. P. (Barrière *et al.* 1999). In Ziama Biosphere Reserve, Guinea, the commonest species in primary forest (32%, $n = 500$, 11 spp.) and secondary forest (28.4%, $n = 509$, 10 spp.), but uncommon in young forest plantations (8%, $n = 303$, 10 spp.) and fields (6%, $n = 272$, 9 spp.) (P. Barrière, unpubl.). Surveys with snap traps yield lower values, such as 4.3% in the Mt Nimba area ($n = 96$) (Heim de Balsac 1958).

Crocidura muricauda

Remarks A climbing species, as is *C. dolichura* (Heim de Balsac & Aellen 1958). Diet includes a wide range of invertebrates (Churchfield *et al.* 2004). The commonest prey items (% frequency of occurrence) in 44 stomachs in Taï N. P., Côte d'Ivoire, were representatives of the following taxa: Araneae (55%), ants (44%, several families), Gryllidae (23%), Blattodea (14%), adult Coleoptera (14%) and Lepidoptera larvae (9%). Twelve other taxa were also present (at values less than 7% frequency of occurrence). Most of the prey was 10 mm or less in size.

Conservation IUCN Category: Least Concern.

Rainer Hutterer

Crocidura mutesae UGANDAN SHREW (UGANDAN MUSK SHREW)

Fr. Crocidure d'Uganda; Ger. Uganda-Moschusspitzmaus

Crocidura mutesae Heller, 1910. *Smithson. Misc. Coll.* 56 (15): 3. Kampala, Uganda.

Taxonomy Alternatively assigned to *C. hirta* (Allen 1939) or *C. suahelae* (Heim de Balsac & Meester 1977). Recorded as *C. mutesae* from Central African Republic (Ray & Hutterer 1995). The taxonomic status is far from being settled (Hutterer 2005b), but for the present the species is considered to be valid pending further studies. A study of 16s rRNA sequences revealed that eight specimens of *C. cf. mutesae* from Central African Republic exhibited eight different haplotypes, five of which were shared with *C. olivieri*. These haplotypes were interspersed with those of *C. olivieri* and *C. goliath* (Quéroutil *et al.* unpubl.). Synonyms: none. Chromosome number: $2n = 50$ (NW DR Congo; R. Hutterer & B. Robbins unpubl.).

Description Very large shrew with thick hairy tail and long pelage. Dorsal and ventral pelage greyish. Feet and tail darker in colour. Hindfeet long and broad. Tail relatively long (ca. 60–75% of HB), dark with tightly packed long bristles (10–12 mm); pilosity 70–80%. Similar to *C. olivieri*, but size is at the lower limit (or below) of the size range of that species. Skull shape similar to *C. olivieri* but less robust and smaller in size (see Hollister 1918: plate 8, figs. 1–2). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (West Central Region, Gabon sub-region) and Eastern Rainforest–Savanna Mosaic. Morphotype described from Kampala, Uganda, and identified as such from SW Central African Republic (Hutterer 1993, Ray 1996, Ray & Hutterer 1995, Morvan *et al.* 1999, Barrière *et al.* 2000) and N DR Congo (R. Hutterer & B. Robbins unpubl.).

Habitat In SW Central African Republic, four (of 12 individuals) were captured in unlogged forest, four in mono-dominant *Gilbertiodendron dewevrei* forest and four in secondary forest along

logging roads. The preferred habitat is where the understorey is relatively open (Ray 1996).

Abundance Comprised 33.3% of shrews ($n = 36$) captured in a mosaic of primary and secondary forest habitats at Salo, Central African Republic (Morvan *et al.* 1999).

Remarks Found in 2.3% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995, Ray 1998).

Conservation IUCN Category: Data Deficient.

Uganda (holotype; Hollister 1918)

Key References Hollister 1918; Ray 1998.**Justina C. Ray & Rainer Hutterer*****Crocidura nana* SOMALI DWARF SHREW**

Fr. Crocidure naine; Ger. Somalia-Zwergspitzmaus

Crocidura nana Dobson, 1890. Ann. Mag. Nat. Hist., ser. 6, 5: 225. Dollo, Somalia.

Taxonomy The name *C. nana* has been given to various small shrews of Somalia, Ethiopia and Egypt, leading to the proposal (Setzer 1957) that *C. nana* is conspecific with *C. religiosa* (which it does not antedate), a conclusion followed by Heim de Balsac & Mein (1971) and Osborn & Helmy (1980). However, the holotype of *C. nana* is a juvenile of a species that is larger than the holotype of *C. religiosa* (Hutterer 1993), and hence the proposal that *C. nana* is conspecific with *C. religiosa* is not acceptable (see Corbet 1978, Hutterer 1993). The relationship of *C. nana* to other very small species has yet to be clarified. Synonyms: none. Chromosome number: not known.

Description Minute shrew. Dorsal hairs short (3–4 mm). Dorsal pelage and flanks slaty-brown. Ventral pelage greyish-white. Upper surface of fore- and hindfeet white. Tail relatively long (ca. 75% of HB), finely haired, dull brown above, white below; numerous whitish bristles on tail. Pilosity 90%. Skull very small with markedly flattened braincase; maxillary region rather narrow; teeth very small; third upper unicuspid a little broader than second (Dollman 1916); talonid of third lower molar reduced to a single cusp. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded at lower altitudes in Somalia and Ethiopia (Heim de Balsac & Meester 1977).

Habitat Little information; appears to inhabit dry grassland and scrub.

Abundance No information; rarely collected.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Crocidura nanilla SAVANNA DWARF SHREW (TINY WHITE-TOOTHED SHREW)

Fr. Crocidure naine de savane; Ger. Savannen Zwergspitzmaus

Crocidura nanilla Thomas, 1909. Ann. Mag. Nat. Hist., ser. 8, 4: 499. Uganda, probably Entebbe.

Taxonomy Determination of this species is difficult because of its similarity to *C. pasha* (Heim de Balsac & Verschuren 1968). Synonyms: *denti*, *nancilla* (*lapsus* for *nanilla*), *rudolfi*. Subspecies: none. Chromosome number: uncertain. (Maddalena & Ruedi 1994, quoted by Hutterer 2005b, give a chromosome number of $2n = 42$, $FN = 74$ from Côte d'Ivoire, a location which is not considered to be within the range of the species.)

Description Minute to very small dark shrew. Pelage short and dense (hairs ca. 3 mm). Dorsal pelage dark greyish-brown to dark blackish-brown; hairs brown on terminal third. Ventral pelage medium grey, paler than dorsal pelage; hairs grey on basal half, pale grey to whitish-grey on terminal half. Colours of dorsal and ventral pelage merge on lower flanks. Colour of head similar to dorsal pelage. Chin and throat white or grey. Fore- and hindfeet dark brown, well covered with short hairs. Tail relatively long (ca. 70% of HB), dark brown above, paler below; pilosity 85%. Dorsal surface of skull convex, and crowns of teeth relatively high (Heim de Balsac 1968a). First incisor long and hooked. Third molar medium. Nipples: not known.

Geographic Variation Pelage colour varies geographically: dorsal pelage dark (e.g. Guinea) to grey with slight rufous tinge (Senegal).

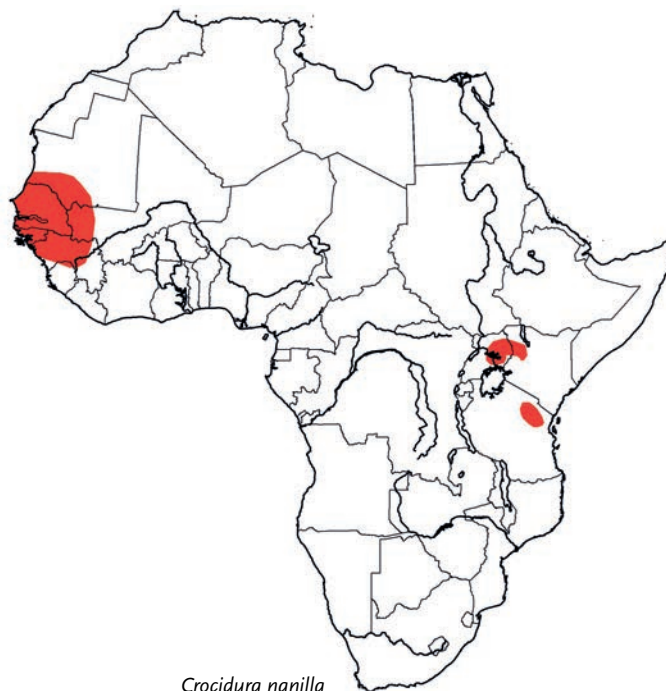

Distribution Endemic to Africa. Sahel and Sudan BZs of West Africa; Eastern Rainforest–Savanna Mosaic and part of Somalia–Masai BZ of eastern Africa. Distribution very disjunct. Recorded from Mauritania to Kenya, Uganda and Tanzania. Limits of distribution uncertain.

Habitat Dry and moist savanna (Hutterer 1993). One individual was found in irrigated crops at Richard-Toll, Senegal (L. Granjon unpubl.).

Abundance No detailed information; rarely captured. Only one specimen captured (out of 172 shrews, 13 spp.) in Garamba N. P., DR Congo (Heim de Balsac & Verschuren 1968).

Remarks Remains of this species (and the similar *C. pasha*) found in owl pellets in Kagera N. P., Rwanda (Heim de Balsac & Verschuren 1968).

Conservation IUCN Category: Least Concern.

D. C. D. Happold

Crocidura nigeriae NIGERIAN SHREW (NIGERIAN MUSK SHREW)

Fr. Crocidure du Nigeria; Ger. Nigeria-Moschusspitzmaus

Crocidura nigeriae Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 524. Asaba ('150 miles up the Niger'), Nigeria.

Taxonomy Very similar in size and colour to *C. longipes*, *C. grandiceps* and *C. foxi*. Previously referred to as *C. occidentalis nigeriae* and *C. poensis nigeriae* (e.g. Happold 1977). Formerly included in *poensis* (*C. p. nigeriae*) but see Heim de Balsac (1957b), Meylan & Vogel

(1982) and Hutterer & Happold (1983). Both *C. nigeriae* and *C. poensis* show considerable variation in colour, specimens of both species from Cameroon being much darker than those from Nigeria. Size and shape of skull, and karyotype, provide distinguishing characters.

Karyotype is identical to that of *C. batesi*, and the two species may be conspecific (Hutterer 2005b). Synonyms: none. Chromosome number: $2n = 50$, $FN = 76$ (Meylan & Vogel 1982).

Description Large shrew. Dorsal pelage very dark brown with a grizzled appearance. Ventral pelage paler, dark grey or greyish-brown. Tail relatively long (60–70% of HB), dark with small black hairs; pilosity 65%. Skull large and flat in profile, with a broad maxillary region and a broad braincase. Third upper molar large, not reduced. Similar to *C. poensis* (paler pelage, hindfoot slightly longer, and tail slightly longer in *C. nigeriae*; see Hutterer & Happold 1983). Nipples: not known.

Geographic Variation Considerable variation in colour is evident, specimens from Cameroon being much darker than those from Nigeria.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Eastern Nigeria and Western Nigeria sub-regions] and Western Region [Ghanaian sub-region]), Northern Rainforest–Savanna Mosaic, and Guinea Savanna BZ. Recorded from W Cameroon, Nigeria, Ghana and Côte d'Ivoire. Bioko I. Distribution disjunct.

Habitat Widespread in rainforest habitats but also recorded in farmlands and grasslands in the Rainforest BZ, and some relict forests in the Rainforest–Savanna Mosaic and Guinea Savanna BZ in Nigeria (Hutterer & Happold 1983, Happold 1987). Recorded only in northern Guinea Savanna in Ghana (Decher *et al.* 1997). Found at 600 m on Mt Cameroon (Heim de Balsac 1957b).

Abundance Uncertain. Some of specimens recorded as *C. poensis* by Happold (1977) may be this species (see *C. poensis*).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.
Widespread and reported to be relatively common.

Crociodura nigricans BLACKISH SHREW (BLACKISH WHITE-TOOTHED SHREW)

Fr. Crocidure d'Angola; Ger. Schwarze Weißzahnschmaus

Crociodura nigricans Bocage, 1889. J. Sci. Math. Phys. Nat. Lisboa (2) 1: 28. Quindumbo, Benguela District, Angola.

Taxonomy Status uncertain; considered to be unidentifiable by Heim de Balsac & Meester (1977) but accepted as a species by Crawford-Cabral (1987) and Hutterer (2005a). Synonyms: none. Chromosome number: not known.

Description Small–medium shrew. Dorsal pelage blackish-blue, slate-grey. Ventral pelage paler. Tail relatively long (ca. 75%

of HB); pilosity ca. 60%. Talonid of M³ lacks a fovea. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded only from Angola.

Habitat Mountainous region of central Angolan plateau (Crawford-Cabral 1987). Reports of *C. nigricans* occurring widely in eastern Africa cannot be confirmed due to the uncertain status of this species.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.
Species insufficiently known.

Crocidura nigrofuscus AFRICAN BLACK SHREW

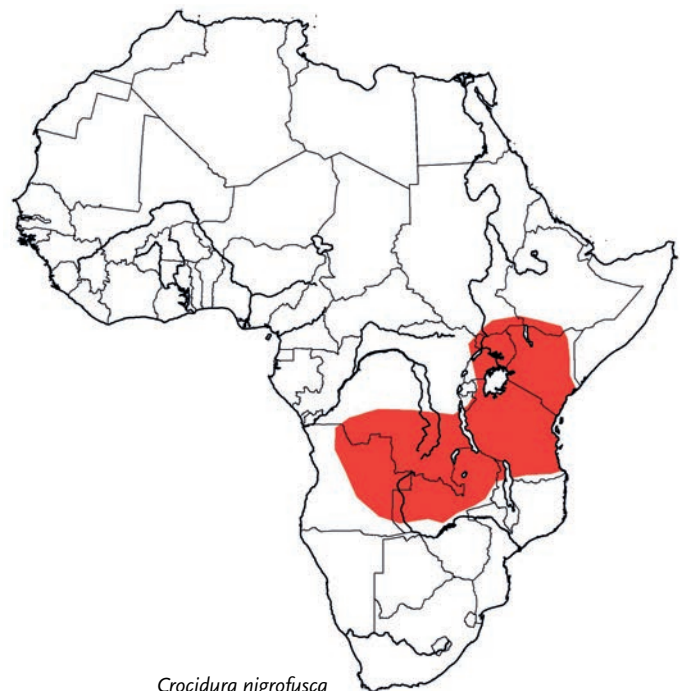

Fr. Crocidure noirâtre; Ger. Afrikanische Schwarzspitzmaus

Crocidura nigrofuscus Matschie, 1895. Säugetiere Deutsch-Ost-Afrikas, p. 33. 'Wukalala, Kinyawanga im Westen des Semliki' (= Semliki Valley, DR Congo).

Taxonomy The species has been quoted under various names and still requires careful systematic revision (Hutterer 2005b). Referred to as *C. luluae* and *C. zaodon* by Heim de Balsac & Meester (1977), and as *C. ansorgei*, *C. nilotica* and *C. zena* by Gureev (1979). Synonyms: *ansorgei*, *cabrerai*, *kempi*, *lakiundae*, *luluae*, *nilotica*, *nyikae*, *provocax*, *zaodon*, *zena*. Subspecies: none. Chromosome number: 2n = 48, FN = 78 (Maddalena & Ruedi 1994). In an allozyme study of 21 African and European species of *Crocidura* (Maddalena 1990a), *C. nigrofuscus* clustered with *C. hildegardae*, *C. poensis* and *C. theresae*.

Description Medium-sized very dark shrew. Pelage soft and dense with silky sheen; hairs 4–5 mm. Dorsal pelage very dark blackish-brown or black; hairs grey at base with dark brown to blackish tip. Ventral pelage similar to dorsal pelage; may be slightly paler. Ears darkly pigmented. Tail relatively long (ca. 75% of HB), black, not bicoloured; pilosity 80–90%. Skull elongated and without sharp edges; braincase oval in dorsal view; dorsal profile straight in lateral view (depicted in Heim de Balsac & Verschuren 1968, fig. 7). First upper incisor short. Third molar medium. Nipples: not known.

Geographic Variation There exist differences in size between geographical samples, but the amount of variation has not been studied. Dippenaar (1982) demonstrated morphometric differences between *C. nigrofuscus* (as *C. zaodon*) and *C. turba* in Zambia.

Crocidura nigrofuscus

Distribution Endemic to Africa. Zambesian Woodland BZ and parts of Somalia–Masai Bushland BZ and Eastern Rainforest–Savanna Mosaic. Recorded from S Ethiopia, S Sudan, most of East Africa, Zambia, Angola and C and S DR Congo. May also occur in Cameroon (Hutterer 2005b). Detailed distribution maps or records (under the name *zaodon*) available for Zambia (Ansell 1978), Malawi (Ansell & Dowsett 1988), Kenya (Aggundey & Schlitter 1986) and Uganda (Hollister 1918).

Habitat Damp habitats near water-courses (Ansell & Dowsett 1988, as *C. zaodon*). Also secondary forest, forest patches, swampy areas in forest–savanna mosaic (Rwanda), and montane forest (S Sudan).

Abundance Uncertain; widely distributed but does not occur in high numbers. In SE Kenya, six individuals (2%, $n = 302$ shrews) were captured in 13 forest fragments (Oguge *et al.* 2004).

Remarks The species represents a general type of terrestrial shrew. Mean litter-size 3.3 (T. Maddalena, in Innes 1994); two embryos reported from Garamba Parc, NE DR Congo (Heim de Balsac & Verschuren 1968).

Conservation IUCN Category: Least Concern.

Rainer Hutterer

Crocidura nimbae NIMBA SHREW

Fr. Crocidure du Mont Nimba; Ger. Nimba-Spitzmaus

Crocidura nimbae Heim de Balsac, 1956. Mammalia 20: 131. Zouguépo, Mt Nimba, Guinea.

Taxonomy A distinct species, now known not to be conspecific with *C. wimmeri* (Hutterer 1993, 2005a; *contra* Hutterer 1983a). Synonyms: none. Chromosome number: not known. (Note: the record of $2n = 46$, $FN = 68$ from a specimen referred to as *C. cf. nimbae* from Yealé, Côte d'Ivoire (Meylan & Vogel 1982) is incorrect since the specimen represents *C. grandiceps* (Hutterer 1983a, Schlitter *et al.* 1999).

Description Medium-sized dark shrew with relatively short tail. Pelage short and dense with silky sheen; hairs 3 mm. Dorsal pelage dark brownish-grey to grey, with sparse flecking; hairs dark grey at base becoming browner towards tip; some hairs with pale tip. Ventral pelage slightly paler and greyer than dorsal pelage; hairs grey on basal half, brownish-grey on terminal half, sometimes with whitish tip. Ears conspicuous, not concealed by pelage. Flank gland visible as small oval patch of bare skin. Fore- and hindfeet flesh-coloured, with sparse short brown hairs on upper surface; whitish hairs on toes. Tail relatively short (ca. 40% of HB), bicoloured, dark brownish-grey above, paler ventrally; pilosity ca. 70%. First incisor long and hooked. Third molar narrow to medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ. Recorded from Sierra Leone, SE Guinea, Liberia and W Côte d'Ivoire.

Habitat Sub-montane and lowland rainforest. Often with a preference for marshy habitats (Heim de Balsac 1956a, 1958).

Abundance Uncommon or rare. In Taï N. P., Côte d'Ivoire, comprised 4% of shrews in several habitats ($n = 553$ shrews; fifth

commonest species; 10 spp.) (Churchfield *et al.* 2004), 3.6% in forest ($n = 390$ shrews, 9 spp.) and 4.3% in cocoa–coffee plantations ($n = 140$ shrews, 7 spp.) (Barrière *et al.* 1999). In Ziam Biosphere Reserve, Guinea, it was very rare or absent: percentage occurrences were 0.6% in secondary forest ($n = 509$ shrews, 10 spp.), 0.2% in primary forest ($n = 500$, 11 spp.) and 0.2% in old forest plantations ($n = 441$ shrews, 9 spp.). The species was not recorded in old fallow

Crocidura nimbae

land, young forest plantations and fields ($n = 484$ shrews, 9 spp.; 303 shrews, 10 spp.; and $n = 272$, 9 spp., respectively) (P. Barrière unpubl.).

Remarks Primarily insectivorous, with lesser amounts of other invertebrates. In Tâi N. P. feeds on nine groups of invertebrates; the commonest food items (as assessed by frequency of occurrence in stomach contents, in order of frequency) were Formicidae (53%), adult Coleoptera (41%), Araneae (29%), Diplopoda (18%), Isopoda (17%), Blattodea (12%) and Heteroptera, Isoptera and Mantidae (6% each) (Churchfield *et al.* 2004).

Conservation IUCN Category: Near Threatened.

Listed as a species of conservation concern by Nicoll & Rathbun (1990).

Crocidura niobe NIOBE'S SHREW

Fr. Crocidure de Niobé; Ger. Niobes Spitzmaus

Crocidura niobe Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 138. Mubuku Valley, E Rwenzori, Uganda. 1829 m.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Small–medium dark shrew with slight silver mottling on dark greyish back. Hairs short, ca. 5 mm on back. Dorsal hairs slate-grey at base (80%), brownish at tip (20%). Ventral pelage slightly paler. Fore- and hindfeet pale brown. Claws on forefeet slightly shorter than on hindfeet. Tail relatively very long (ca. 82% of HB), slender, uniformly blackish, sometimes with white tip; pilosity: 0–10%. Skull with low braincase; muzzle stout and conical; unicuspid broader than long. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa Afromontane–Afroalpine BZ associated with the Albertine Rift Valley. Recorded from Rwenzori Mts of both Uganda and DR Congo. Also recorded in Uganda (Bwindi–Impenetrable N. P., Mgahinga Gorilla N. P. [3000 m]), Burundi (Kibira N. P. and Bururi F. R. [1950–2250 m]) and E DR Congo (Irangi [800–900 m]). Not yet recorded from Rwanda, but likely to occur in Nyungwe N. P. and Parc National des Volcans. A specimen from Ethiopia (Corbet & Yalden 1972) is probably *C. harena* or a closely related species (Hutterer & Yalden 1990).

Habitat In Irangi, E DR Congo, found in montane rainforest, secondary forest and adjacent to cultivated areas (Dieterlen & Heim de Balsac 1979). In the Rwenzori Mts, recorded in elephant grass below the forest (Thomas & Wroughton 1910) as well as montane forest at 1920 m (Kerbis Peterhans *et al.* 1998). In Kibira N. P., favours mesic habitats along shallow streams and sedge marshes. In Mgahinga Gorilla N. P., collected within and adjacent to sedge marshes at a high altitude.

Abundance Generally rare, but may be common in favoured locations; e.g. comprised 44% of shrews and was the commonest species ($n = 23$, 7 spp.) at Kyoha River, Rwenzori Mts, but did not occur at five other localities on these mountains (Kerbis Peterhans *et al.* 1998). Comprised 40% of the shrew fauna ($n = 10$) along the Nyabikona River in Kibira N. P.

Remarks Nocturnal. Stomach contents of five specimens from Burundi contained remains of Araneida, Diptera, Chilopoda

Crocidura niobe

(including *Chilopoda mesostigmata*) and Coleoptera (adult & larva). Pregnant ♀♀ recorded in Mar (Mgahinga Gorilla N. P.); Apr (Irangi, E DR Congo); May and Aug (Kibira N. P.), Burundi; and Nov (Rwenzori Mountains N. P., Uganda). Records refer to only one to three ♀♀ at each occasion. Embryo number: 1–4.

Conservation IUCN Category: Near Threatened.

Crocidura obscurior WEST AFRICAN PYGMY SHREW

Fr. Crocidure obscure; Ger. Westafrika-Zwergspitzmaus

Crocidura obscurior Heim de Balsac, 1958. Mém. Inst. Fr. Afr. Noire 53: 328. Mt Nimba, Guinea; montane prairie.

Taxonomy Described as a subspecies of *C. bottegi* (see Heim de Balsac & Meester 1977); now considered as valid species (Hutterer 2005b). (The name *C. bottegi* is now restricted to populations found only in Ethiopia.) Synonyms: *eburnea*. Subspecies: none. Chromosome number: 2n = 36, FN = 56 (Côte d'Ivoire; Maddalena & Ruedi 1994), and 2n = 40, FN = 60 (Meylan 1971 as *C. bottegi*).

Description Minute to very small dark brown shrew. Pelage soft, dense and velvety; hairs 1–2 mm. Dorsal pelage dark brown, with slight russet tinge and silky sheen; hairs almost unicoloured, some with dark brown tip. Ventral pelage greyish-brown. Head similar to dorsal pelage. Ears darkly pigmented, not concealed by pelage; appear naked but covered with short dark hairs. Chin and throat similar to ventral pelage. Tail relatively long (ca. 60–70% of HB), dark brown above, slightly paler below; long white hairs on tail – pilosity ca. 50%. Braincase high-domed. First upper incisor long and hooked. Third upper molar wide. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (Western Region and W Nigeria). Recorded from Sierra Leone, Côte d'Ivoire, S Guinea and Ghana; probably also W Nigeria. Not known to occur east of Nigeria (*contra* Heim de Balsac & Meester 1977).

Habitat Rainforest and on edges of forest. Specimens (as *C. bottegi eburnea*) found in swampy habitats (Adiopoudoumé, Côte d'Ivoire), in or near forest (near Mt Nimba), and in highland grasslands (near a wooded ravine at 1600 m) (Heim de Balsac & Aellen 1958).

Abundance Common in most habitats. In Taï N. P., Côte d'Ivoire, it was the commonest species of shrew in forest and plantations, comprising 38.2% (n = 390, 9 spp.) of shrews in forest, and 37.2% (n = 140, 7 spp.) in cocoa–coffee plantations (Barrière *et al.* 1999). In Ziama Biosphere Reserve, Guinea, it was the commonest species of shrew in young forest plantations and fallow land (39.6%, n = 303, 10 spp. and 33.6%, n = 484, 9 spp., respectively). In primary and secondary forests at Ziama, it was co-dominant with *C. muricauda*

(30.4%, n = 500, 11 spp. and 27.6%, n = 509, 10 spp., respectively), and less common in old forest plantations and fields (25.2%, n = 441, 9 spp. and 14.8%, n = 272, 9 spp., respectively) (P. Barrière unpubl.).

Remarks The commonest prey items (% frequency of occurrence) in 59 stomachs in Taï N.P., Côte d'Ivoire, were representatives of the following taxa: Formicidae (71%), Araneae (52.5%), Gryllidae (17%), Coleoptera adults (15.3%), Diplopoda (11.9%), Isopoda (10.2%), Blattodea (8.5%), Heteroptera (7.7%), Isoptera (5.1%), Lepidoptera adults (5.1%) and Coleoptera larvae (3.4%). Diptera adults, Lepidoptera larvae, Gastropoda, Lumbricidae, plant material and Acrididae were represented by lower percentage occurrences. Noteworthy features are the presence of small amounts of earthworms and plant material in the diet, and the exceptionally long intestine for a species of this size (Churchfield *et al.* 2004).

Crociodura olivieri AFRICAN GIANT SHREW (MANN'S MUSK SHREW, EUCHAREENA'S MUSK SHREW)

Fr. Crocidure grande africaine; Ger. Große Afrikanische Riesenspitzmaus

Crociodura olivieri (Lesson, 1827). Manuel de Mammalogie, p. 121. Sakkara, Egypt; neotype collected near Giza.

Taxonomy Originally described in the genus *Sorex*. First described from embalmed animals found in Egyptian tombs at Sakkara. *Crociodura olivieri* is the valid name for the large shrews previously known as *C. flavescens* (now the valid name for a smaller species restricted to South Africa). Synonyms: *aequatorialis*, *anchietae*, *atlantis*, *bueae*, *cara*, *cinereoaeana*, *daphnia*, *darfurea*, *detae*, *doriana*, *ferruginea*, *fuscusa*, *giffardi*, *guineensis*, *hansruppi*, *hedenborgi*, *hedenborgiana*, *hera*, *herero*, *kijabae*, *kivu*, *luluana*, *manni*, *martienseni*, *nyansae*, *petersii*, *occidentalis*, *odorata*, *spurelli*, *suruae*, *tatiana*, *toritensis*, *zuleika*. Many of these names have been used as subspecies, or have been considered as allospecies of a *flavescens* superspecies (Hutterer 2005b). Many authors also distinguished between pale (*occidentalis*, *manni*, *spurelli*) and black (*giffardi*, *hedenborgiana*, *martienseni*, *odorata*) colour morphs, regarding them as different species; biochemical evidence has shown that they are merely colour morphs of a single and highly variable species (Maddalena 1990a). Subspecies: none recognized here; but see above and Hutterer (2005b). Chromosome number: 2n = 50, FN = 66, aFN = 62 (Meylan & Vogel 1982).

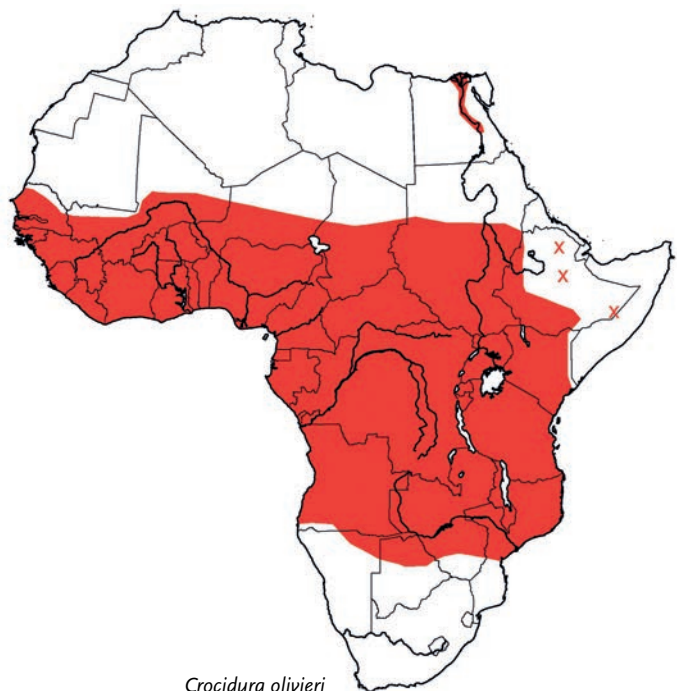

Description Very large shrew, highly variable in colour and size (see below). Dorsal pelage reddish-brown to dark brown or black. Ventral pelage buffy-brown to dark grey. Tail relatively long (70–80% of HB), thick, with many short bristles; pilosity ca. 100%. Skull large, heavy and flat in profile, with large rostrum but relatively small cranium. Rostrum, maxilla and braincase broad but interorbital constriction long and narrow. Teeth large and heavy, particularly the incisors. Well-developed lateral flank glands exude a sweet, musky odour, particularly strong and pungent in West African forms (*manni* and *odorata*). Nipples: 1 + 2 = 6 (in some specimens nipples are equally spaced on each side of the ventral surface).

Geographic Variation Very variable in respect of size (see below) and pelage colour. West African forms (*manni*, *odorata*) are the largest (HB: 98–154 mm; adult WT: 37–78 g). Pelage colour ranges from reddish-brown to dark brown or blackish dorsally, and from buffy-brown to dark grey ventrally (Maddalena 1990a).

Distribution Endemic to Africa. Widely distributed throughout many biotic zones from the Sahel Savanna BZ to the Rainforest BZ,

and in most of the Somalia–Masai BZ and the Zambezian Woodland BZ. Recorded from Senegal eastwards to Sudan and Ethiopia, and southwards towards southern Africa. Found in the Nile Valley of Egypt but not in the arid Sahara Desert nor the arid parts of Somalia and Ethiopia. Occurs along Okavango and Chobe Rivers, and in Okavango Swamp in northern Botswana but its distribution further south is apparently limited by ecological factors, particularly aridity. Occurs from close to sea level to high up on mountains. Recorded on Mts Kenya, Elgon and Umengo, and on the Aberdare Ranges (Aggundey & Schlitter 1986), and at altitudes up to 3300 m in DR Congo and Kenya (Dieterlen & Heim de Balsac 1979, Aggundey & Schlitter 1986).

Habitat Common and widespread, mostly in well-vegetated moist habitats including lowland and montane evergreen forest, riverine and flood-plain grassland and swamp (Sheppe & Osborne 1971, Sheppe 1973) but also in scrub and in burnt and grazed

Crociodura olivieri

grassland (Delany 1964a). Occasionally found in pine plantations and montane grasslands (Happold & Happold 1986). Common in farmland, plantations, around houses and food stores (Delany 1964a, Hutterer *et al.* 1987, Brosset 1988).

Abundance No data on population densities. A frequent but variable contributor to sorcid communities. In DR Congo, comprised 8% of shrew captures in montane habitats at 1900–3300 m (10 spp.), 77% in rainforest at 800–900 m (7 spp.) and 31% in cultivated areas (9 spp.) (Dieterlen & Heim de Balsac 1979). In Uganda, it constituted 20–80% of captures in communities of 2–8 shrew species (Delany 1964a), but only 8.5% of shrew captures (4 spp.) in the Pare Mts, Tanzania (Stanley *et al.* 1996a) and 3.1% in Gabon (Brosset 1988).

Adaptations Terrestrial, and adaptable, and able to occupy many different habitats and to live commensally with humans. Wild and captive individuals almost completely nocturnal with peaks of activity just before dawn (Vogel *et al.* 1981, Brosset 1988). Moulting shrews found in Mar, May, Jul and Aug in Zambia (Sheppe 1973).

Foraging and Food Feeds on invertebrates, particularly arthropods, and possibly carrion. Analyses of stomach contents ($n = 16$) from rainforest in DR Congo showed that major prey comprised Formicidae (20% by composition), Coleoptera and Diplopoda (each 16%), Isoptera and Araneae (each 12%) with smaller amounts of Acrididae and insect larvae. Prey were 3 mm to >30 mm in length with 67% being <10 mm (Dudu *et al.* 2005). Food energy consumption was 2.02–2.56 kJ/g/day (mean 2.27 kJ) in captive animals weighing 26–37 g (Hunkeler & Hunkeler 1970). Mean oxygen consumption was 2.07 kJ/g/h (Vogel 1976).

Social and Reproductive Behaviour Essentially solitary but individuals often live in close proximity. They utter loud shrieks and churls when angry or threatened.

Reproduction and Population Structure Breeding activity varies according to locality. In DR Congo, pregnant ♀♀ found in all months, but breeding declined during dry season (Dieterlen & Heim de Balsac 1979). Pregnant ♀♀ caught in dry and wet seasons in Zambia (Sheppe 1973). In Uganda, all ♀♀ examined in Jul–Aug, and one ♀ in Dec, were pregnant (Delany 1964a). Embryo number: 4 (1–5) in eastern Africa (Delany 1964b, Sheppe 1973, Dieterlen & Heim de Balsac 1979), and 2 (1–4) in central and western Africa (Dubost 1968, Happold 1987). Usually four young/litter in Nigeria (Happold 1987). Breeding ♀♀ captured in and around human settlements in Gabon have greater fecundity (3–4 embryos) than those in natural habitats (1–2 embryos) (Dubost 1968). Pregnant and parous ♀♀ weighed 34–57 g, non-breeding females 35–42 g (Sheppe 1973). Testis length 4–8 mm, width 3 mm (Delany 1964b, Stanley *et al.* 1996a). Sex ratio of captured animals ca. 1 : 1 ($n = 32$)

in eastern Africa (Sheppe 1973) but male-biased (66% ♂ to 34% ♀) in central Africa (Dieterlen & Heim de Balsac 1979). Little is known about other aspects of the life history of the species.

Predators, Parasites and Diseases Main predators are raptors, particularly owls (including *Tyto alba* and *Bubo africanus*), and small carnivores such as mongooses, genets and wild cats (Demeter 1981, Ray & Hutterer 1995). Contributed 5% and 15–23% to the diets of *T. alba* and *T. capensis*, respectively, in Malawi (Hanney 1962, Happold & Happold 1986). Even the large and odoriferous *manni* and *odorata* have been found in owl pellets. Comprised 0.3% of shrews (16 spp.) identified in carnivore scats from the Central African Republic (Ray & Hutterer 1995). Host to a diversity of helminths.

Conservation IUCN Category: Least Concern.

A common and widespread species of no immediate conservation concern.

Crocidura parvipes SMALL-FOOTED SHREW

Fr. Crocidure à petits pieds; Ger. Kleinfüßige Savannenspitzmaus

Crocidura parvipes Osgood, 1910. Field Mus. Nat. Hist. Publ., Zool. Ser. 10: 19. Voi, Kenya.

Taxonomy Subgenus *Afrosorex* (Hutterer 1986a). Synonyms: *boydi*, *chitauensis*, *cuanzensis*, *katharina*, *lutrella*, *nisa*. Subspecies: none. Chromosome number: $2n = 50$ (Bannikova *et al.* 2001; Ethiopia), $2n = 52$, $FN = 66$ (Schlitter *et al.* 1999; Cameroon).

Description Small-medium greyish-brown shrew. Pelage soft and dense with silky sheen; hairs ca. 4 mm. Dorsal pelage mid-brown, washed with pale brownish-grey; hairs medium grey on basal two-thirds, pale brownish-grey subterminal band, and brown at tip (see also below). Ventral pelage creamy-grey, sometimes silvery-white; hairs grey with creamy-grey at tip. Appears to be clear delineation between colour of dorsal and ventral pelage. Flank gland elongated, covered by short white hairs. Ears large and comparatively conspicuous, not concealed by pelage. Fore- and hindfeet flesh-coloured, covered with short pale brown or creamy hair. Hindfeet relatively short. Tail of medium relative length (ca. 45–60% of HB), thick at base and tapering towards tip; bicoloured, medium brown above, flesh-coloured below; pilosity ca. 85%. First incisor moderately long and slightly hooked. Third molar medium to narrow. Nipples: not known.

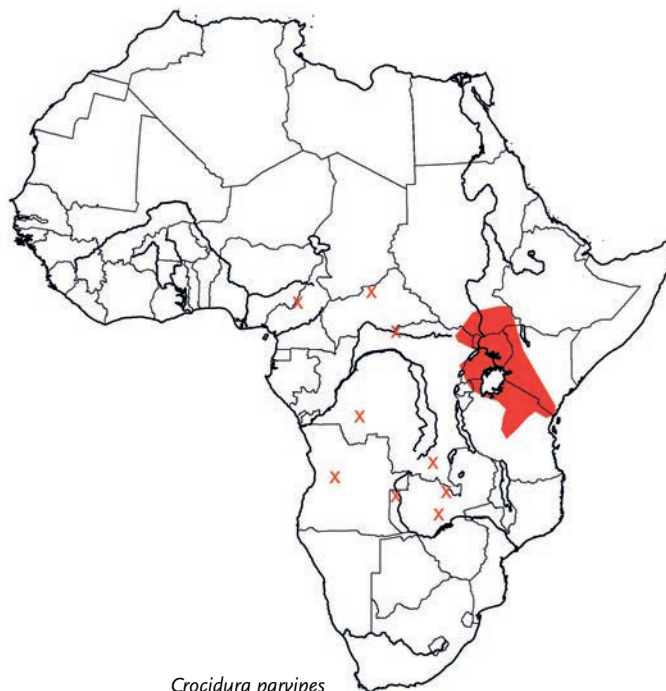

Geographic Variation Dorsal pelage varies in colour from 'drab grey' to greyish-brown and brown (Hutterer 1986a). Considerable variation in size may indicate that there may be more than one species involved (Hutterer 2005b).

Distribution Endemic to Africa. Primarily Eastern Rainforest–Savanna Mosaic, and parts of the Guinea, Zambezian Woodland and Somalia–Masai Bushland BZs of eastern Africa; isolated scattered records throughout central Africa. Recorded from Cameroon, Central African Republic, S Sudan, Uganda, Ethiopia, Kenya, Tanzania, DR Congo, Zambia and Angola. Limits of distribution uncertain.

Habitat Savanna. In Garamba N. P., DR Congo, usually found in dry savanna habitats and occasionally in gallery forest (Heim de Balsac & Verschuren 1968; as *C. boydi*).

Abundance No information.

Remarks Little is known about this species. Remains have been found in the pellets of Barn Owls *Tyto alba* (Heim de Balsac & Verschuren 1968).

Crocidura pasha SAHELIAN TINY SHREW

Fr. Crocidure naine du Soudan; Ger. Sahel-Zwergspitzmaus

Crocidura pasha Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 517. 1916. Ann. Mag. Nat. Hist., ser. 8, 17: 195. Atbara River, Sudan.

Taxonomy Similar to *C. nana* and *C. nanilla* but with a smaller skull. Often confused with *C. nanilla* and *C. lusitania*. Does not include *glebula* (a synonym of *C. fuscomurina*) or *C. planiceps* (see Hutterer & Kock 1983). A specimen from Zunguru, Nigeria, was described as the holotype of *C. glebula* (Dollman 1916) and has been referred to as *C. glebula* by Rosevear (1953) but as *C. pasha glebula* by Heim de Balsac & Meester (1977). Synonyms: none. Chromosome number: not known.

Description Minute shrew. Dorsal pelage cinnamon mottled with grey. Ventral pelage white. Flanks similar to dorsal pelage. Upper surface of fore- and hindfeet whitish-buff. Tail relatively long (ca. 70% of HB), finely haired, cinnamon-brown above, whitish below, with numerous long, white bristle hairs; pilosity ca. 95%. Skull flattened, sides of braincase rather less parallel, more convex. Teeth small; second upper unicuspid slightly smaller in horizontal section than the third, which slightly overlaps it; third upper unicuspid moderately narrow; talonid of third lower molar a single cusp. Nipples: not known.

Geographic Variation None recorded.

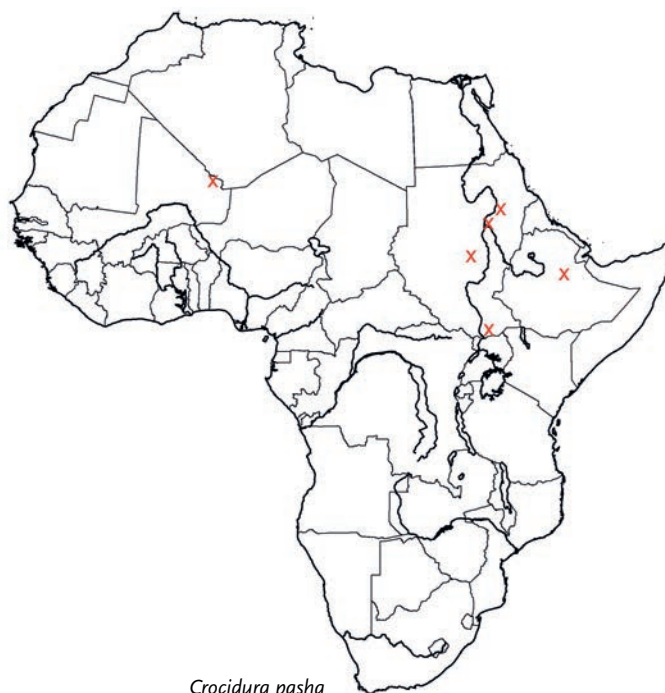

Distribution Endemic to Africa. Sahel Savanna and Sudan Savanna BZs. Widespread in semi-arid habitats, but known populations very disjunct. Recorded in Sudan from Atbara R. (Dollman 1916), Khartoum and Torit (Setzer, 1956) and Nuba Mts (Hutterer & Kock 1983). Also known from Awash N. P., Ethiopia (Demeter 1982) and Adrar des Iforas, N Mali (Dobigny *et al.* 2001).

Habitat Semi-arid savannas.

Abundance Little information. Common in Adrar des Iforas, N Mali (Dobigny *et al.* 2001; see also below).

Remarks Remains of one individual (out 344 shrews) found in pellets of a Spotted Eagle-owl *Bubo africanus* in Awash N. P., Ethiopia (Demeter 1982). The commonest species of shrew (of three species) in owl pellets from Adrar des Iforas (Dobigny *et al.* 2001).

Conservation IUCN Category: Least Concern.
Insufficiently known.

Crocidura phaeura GURAMBA SHREW

Fr. Crocidure du Mont Guramba; Ger. Guramba Spitzmaus

Crocidura phaeura Osgood, 1936. Field Mus. Nat. Hist. Publ., Zool. ser. 20: 228. Mt Guramba (west base), NE of Allata, Sidamo, Ethiopia.

Taxonomy Taxonomic relationships uncertain. Originally described as a subspecies of *C. hildegardeae* (Osgood 1936). Included as a subspecies of *C. hildegardeae* by Yalden *et al.* (1976); now considered a valid species (Hutterer 2005b). Cranial characteristics

place the species close to *C. montis* and *C. fumosa*, both members of the *luna-fumosa* complex (see Dippenaar & Meester 1989). Related to *C. harensa* (Hutterer & Yalden 1990). Synonyms: none. Chromosome number: not known.

Description Small to medium-sized dark shrew, similar to *C. hildegardeae*. Dorsal pelage dark blackish-brown. Ventral pelage similar but slightly paler. Relatively large hindfeet (18.6% HB). Tail of medium relative length (ca. 53% of HB); entirely dark; pilosity not known. Braincase relatively broad and deep. Second unicuspid slightly smaller than third unicuspid (Osgood 1936). M^3 more robust than in any other African *Crocridura* (Dippenaar & Meester 1989). Appreciably smaller than other Ethiopian endemics of the *glassii* group. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Recorded only from Mt Guramba (type locality) (Osgood 1936) and Nechisar N. P. at 1100 m (Duckworth *et al.* 1993). Specimens from four other localities (Sakalla, west of L. Zwai, Arba Minch, and Dolo) originally allocated to *C. phaeura* (Yalden *et al.* 1976) are now considered to represent *C. hildegardeae* (Yalden & Largen 1992).

Habitat Forested localities, including riverine forest at Nachisar (1100 m) and Mt Guramba (2600 m).

Abundance Apparently rare with very restricted geographic range.

Remarks One of five endemic species of shrews (*C. bottegoides*, *C. glassii*, *C. harenna*, *C. lucina*, *C. phaeura*) known only from Ethiopia east of the Rift Valley (Hutterer & Yalden 1990). Apparently no other information available.

Conservation IUCN Category: Endangered.
Previously considered as Critically Endangered.

Crocridura picea CAMEROON SHREW (ASSUMBO SHREW)

Fr. Crocidure d'Assumbo; Ger. Kamerun-Spitzmaus

Crocridura picea Sanderson, 1940. Trans. Zool. Soc. Lond. 24: 682. Tinta, Assumbo, Mamfe Division, Cameroon. 2300 ft (701 m).

Taxonomy Originally described as a subspecies of *C. occidentalis*. Synonyms: none. Chromosome number: $2n = 58$, $FN = 66$ (Schlitter *et al.* 1999).

Description Small–medium dark shrew. Pelage soft and dense with silky sheen; hairs 4–5 mm. Dorsal pelage medium to dark greyish-brown or black with sparse inconspicuous flecking; hairs dark grey on basal two-thirds, brown or greyish-brown on terminal third. Ventral pelage slightly paler and greyer; hairs grey at base; medium grey on terminal third. Ears moderately large and conspicuous, not concealed by pelage. Fore- and hindfeet blackish-brown, with dark brown short hairs; sharp claws. Tail of medium relative length (ca. 55% of HB), blackish-brown, not bicoloured; pilosity ca. 78%. Braincase medium. First upper incisor long and hooked. Third upper molar medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Bamenda Highlands, Cameroon.

Habitat 'False mountain grass; dry locality with sandy soil' (Sanderson 1940).

Abundance Very rare; known only by a few specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Crocidura picea

Crocidura pitmani PITMAN'S SHREW

Fr. Crocidure de Pitman; Ger. Pitmans Spitzmaus

Crocidura pitmani Barclay, 1932. Ann. Mag. Nat. Hist., ser. 10, 10: 440. Maluwe-Serenje District, Zambia. 3800 ft (1158 m).

Taxonomy Similar to but smaller than *C. bicolor*. Placed as synonym of *C. gracilipes* by Ansell (1978). Synonyms: none. Chromosome number: not known.

Conservation IUCN Category: Data Deficient.

Previously assessed as Vulnerable. Major threats are human-induced habitat loss and degradation, and restricted distribution.

Description Very small shrew with comparatively long pelage (hairs 4–5 mm). Dorsal pelage mouse-grey slightly tinged with brown. Ventral pelage paler and slightly flecked with a few white hairs, especially under chin and throat. Dorsal and ventral pelage not clearly delineated at flanks. Upper surface of fore- and hindfeet greyish-brown. Tail relatively long (ca. 72% of HB), unicoloured grey-brown; pilosity ca. 35–40%. Skull relatively large with a broad braincase; third unicuspid larger than second; third upper molar moderately broad, entoconid present on talonid of third lower molar. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded definitively only from the type locality. The location of the holotype is uncertain but is thought to be on the Luomba R. (ca. 13° 30' S, 30° 30' E) (Ansell 1978). Limits uncertain: perhaps occurs throughout C and N Zambia (Hutterer 2005b).

Habitat No information.

Abundance No information.

Remarks Apparently no other information available.

Zambia (holotype; Barclay 1932)

Key Reference Barclay 1932.**S. Churchfield & P. D. Jenkins*****Crocidura planiceps* FLAT-HEADED SHREW**

Fr. Crocidure à tête plate; Ger. Flachkopf-Spitzmaus

Crocidura planiceps Heller, 1910. Smithson. Misc. Coll. 56 (15): 5. Rhino Camp, Lado Enclave, Uganda.

Taxonomy Closely related to and very similar to *C. fuscomurina*, if not conspecific (see Heim de Balsac 1968a, Hutterer 1983b, 2005a). Synonyms: none. Chromosome number: 2n = 44, FN = 72 (Meylan & Vogel 1982).

Description Small to very small shrew similar to *C. fuscomurina*. Dorsal pelage cinnamon-brown to greyish-brown; hairs uniform in colour to roots. Ventral pelage paler, tending to yellowish-grey or silvery-grey. Flank glands distinctly marked by an oblong patch of whitish hair. Feet paler in colour than dorsal pelage. Tail relatively long (72–78% of HB); pilosity 70–80%. Skull smaller and slimmer than that of *C. fuscomurina*, especially in the maxillary region and the braincase. Braincase very flat, with a marked depression at its termination in the interorbital region; the profile of the rostrum ascends slightly anterior to this depression. Upper tooththrow shorter than in *C. fuscomurina*. Nipples: not known.

Geographic Variation Some evidence of local variation in pelage colour and skull size in Nigeria (Hutterer & Happold 1983).

Distribution Endemic to Africa. Guinea Savanna and Sudan Savanna BZs. Recorded from N Nigeria, N DR Congo, Uganda, Sudan and Ethiopia (Hutterer & Happold 1983, Hutterer 2005b). Distribution appears to be disjunct. Limits uncertain.

Habitat In Yankari G. R., N Nigeria, found in *Cyperus* swamp near a stream (Happold 1987).

Abundance No information.

Remarks Some evidence of breeding in Nov in Nigeria. Remains have been found in owl pellets in Nigeria (Hutterer & Happold, 1983).

Conservation IUCN Category: Data Deficient.

S. Churchfield & P. D. Jenkins

Crocidura poensis FRASER'S SHREW (FRASER'S MUSK SHREW)

Fr. Crocidure de Fraser; Ger. Frasers Moschusspitzmaus

Crocidura poensis (Fraser, 1843). Proc. Zool. Soc. Lond. 1842: 200 (publ. 1843). Clarence, Fernando Poo (= Bioko I., Equatorial Guinea).

Taxonomy Originally described in the genus *Sorex*. Definition of this species is uncertain (Hutterer 2005b). Included in *C. dolichura* by Heim de Balsac & Meester (1977) but considered as a distinct species by Hutterer (1993, 2005a). Synonyms: *calabarensis*, *pamela*, *schweitzeri*, *soricoides*, *stampflii*. Subspecies: none. Chromosome number: $2n = 52$, $FN = 70$ (Côte d'Ivoire; Meylan & Vogel 1982).

Description Medium-sized musk shrew. Dorsal pelage dark brown to blackish. Ventral pelage paler, greyish-brown. Ear pinnae prominent. Limbs dark. Tail relatively long (ca. 75% of HB), thin and dark, covered with short bristles; pilosity ca. 50%. Both sexes have oval-shaped lateral scent glands on the flanks, surrounded by short stiff hairs that exude a greasy secretion with a prominent sweet, musky odour (hence 'musk shrew'). Distinguishable from other similar species by sonographic differences in frequency and duration of defence calls (Hutterer & Vogel 1977). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Widely distributed in the Rainforest BZ (Western Region and West Central Region) and Guinea Savanna BZ of West Africa. Recorded from Sierra Leone and Guinea to Cameroon. Also Bioko I. and (extraliminally) Príncipe I.

Habitat Mostly found in primary and secondary lowland evergreen rainforest, forest relicts up to 1000 m. Also occurs in rough grass, farmland, plantations, gardens and around houses.

*Crocidura poensis*

Abundance Frequently the most numerous species in West African shrew communities. It was the most abundant species, comprising 48% ($n = 160$) of forest-dwelling shrews in Gabon (10 spp.; Brosset 1988); and also the most abundant species (equal in abundance with *Sylvisorex schoutedeni*; 29%, $n = 24$; 9 spp.) in Korup N. P., Cameroon (Hutterer & Schlitter 1996). Reported to be common in some rainforest localities in Nigeria (Happold 1987). In Gambari Forest, Nigeria, comprised 29% of shrews (2 spp., $n = 56$) during a mark-recapture study over three years, and 28% over the following five years (2 spp., $n = 29$) (Happold 1977). It was much less common than the other syntopic species (*C. crossi*) (Happold 1977). No data on population densities.

Adaptations Ground-dwelling, adaptable and able to live in anthropogenic habitats and commensally with humans. Mostly nocturnal, increasing in activity before dawn (Vogel *et al.* 1981, Brosset 1988).

Foraging and Food Feeds on invertebrates, particularly arthropods. Major prey items (in order of importance) based on analysis of faecal material from live-trapped shrews in Nigeria ($n = 8$) are species of Gryllidae, Diplopoda, Coleoptera, Heteroptera, Formicidae, Lepidopteran larvae and Araneae (Churchfield 1982). Captive individuals readily ate grasshoppers and mantids. Most prey were 5–20 mm in length but captive shrews took prey up to 50 mm in length. Mean food energy consumption was 3.49 kJ/g body mass/day (range 3.32–3.86, $n = 4$) in captive animals weighing 14–20 g (Hunkeler & Hunkeler 1970). Mean oxygen consumption of captive animals with mean body weight of 16.7 g ($n = 4$) was 1.05 kJ/h (Vogel 1976).

Social and Reproductive Behaviour Primarily solitary and aggressive towards conspecifics, but with partial overlap of home-ranges. Scent is probably important in the social and spatial organization of these highly odoriferous shrews.

Reproduction and Population Structure Little information. Mean embryo number: 3 (range 1–4). Fecundity greater than in other sympatric forest-dwelling crocidurine shrews (Brosset 1988). Pregnant ♀ with three embryos (each 16 mm crown–rump) captured in Jun in Cameroon; testes of males 5–7 mm (Hutterer & Schlitter 1996).

Predators, Parasites and Diseases Main predators are raptors, particularly owls. Shrews, including *C. poensis*, comprised 31% by number and 6% by weight in the diet of Spotted Eagle-owls *Bubo africanus*, and 25–29% by number and 8–16% by weight in the diet of Barn Owls *Tyto alba*, in and around Yankari G. R., Nigeria (Demeter 1981). Also preyed on by mongooses, genets and small cats. Host to a diversity of helminth worms.

Conservation IUCN Category: Least Concern.

Primarily a forest-dwelling species; relatively common, widespread and adaptable, and of no immediate conservation concern.

Crocidura polia POLIA'S SHREW

Fr. Crocidure de Medje; Ger. Polias Spitzmaus

Crocidura polia Hollister, 1916. Bull. Amer. Mus. Nat. Hist. 35: 669. Medje, DR Congo.

Taxonomy Included in *C. dolichura* by Heim de Balsac & Meester (1977). Synonyms: none. Chromosome number: not known.

Description Very small greyish-brown shrew. Dorsal pelage greyish-brown, sparsely speckled with silvery-grey. Ventral pelage pale greyish-brown. Fore- and hindfeet whitish. Tail relatively extremely long (ca. 124% of HB), slightly bicoloured, blackish brown above, paler below; uniquely covered with short hairs, which increase in number and length on the terminal half to form a distinct white brush at tip. Skull profile flat, rising gently from rostrum to occiput. First upper incisor small. Uniscupids pointed; first uniscupid larger than second and third; second and third subequal. Third upper molar medium. Nipples: not known.

Geographic Variation None.

Distribution Endemic to Africa. Rainforest BZ/Northern Rainforest–Savanna Mosaic. Known only from the type locality at Medje, DR Congo.

Habitat Not known. The vegetation at Medje is a mosaic of rainforest and savanna.

Abundance Very rare. Known only by the holotype.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

***Crocidura raineyi* RAINEY'S SHREW**

Fr. Crocidure de Rainey (Crocidure de Mt Garguez); Ger. Raineys Spitzmaus

Crocidura raineyi Heller, 1912. Smithson. Misc. Coll. 60 (12): 7–8. North Creek, Mt Garguez, Kenya (= Warges, Kenya).

Taxonomy A species of the *luna-fumosa* group (Dippenaar & Meester 1989); the largest species in the group. Not a synonym of *C. luna* as given by Heim de Balsac & Meester (1977). Synonyms: none. Chromosome number: not known.

Description Large brownish-grey shrew. Dorsal pelage grizzled brownish-grey. Ventral pelage paler than dorsal pelage. Fore- and hindfeet very pale yellowish-brown (not black). Tail relatively long (ca. 69% of HB); bicoloured, brownish-grey above, whitish below; pilosity 61–71%. Skull medium-sized, braincase narrow and low. Unicuspid subequal. Upper third molar robust. (Description after Dippenaar & Meester 1989.) Nipples: not known.

Geographic Variation None.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from the type locality at Mt Garguez, Kenya.

Habitat No information.

Abundance Very rare. Known only from the holotype and eight paratypes collected in 1911.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient; formerly Critically Endangered.

*Range not given

Key Reference Dippenaar & Meester 1989.**Rainer Hutterer*****Crocidura religiosa* EGYPTIAN PYGMY SHREW**

Fr. Crocidure naine d'Égypte; Ger. Ägypten-Zwergspitzmaus

Crocidura religiosa (L. Geoffroy, 1827). Mem. Mus. Hist. Nat. Paris 15: 128. Giza, Egypt.

Taxonomy Originally described as *Sorex religiosa* from embalmed specimens from ancient Egyptian tombs at Thebes. Referred to as *C. nana* by Osborn & Helmy (1980), a name that has been applied to various small shrews of Somalia, Ethiopia and Egypt (see Hutterer 2005b for discussion). The name *religiosa* is now restricted to the small endemic shrew of the Nile Valley in Egypt (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Very small grey shrew. Dorsal pelage greyish with tinge of brown. Ventral pelage pale grey; hairs grey at base, white

at tip. Chin and throat paler than ventral pelage. Fore- and hindfeet whitish. Tail relatively long (ca. 65% of HB), bicoloured, grey above, whitish below; pilosity uncertain ('bristles numerous'). Skull small and delicate, and rather 'flat'. (Description modified from Osborn & Helmy 1980.) Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sahara Arid BZ. Recorded only in Egypt in the southern part of the Nile delta near Giza, and at

Thebes. May occur along Nile Valley between Giza and Thebes.

Habitat Recorded under stones, bricks and clumps of earth in moist cultivated fields (Hoogstraal 1962); also found along canal banks and under piles of grass, cotton and corn stalks (Osborn & Helmy 1980). Nest made of cotton bolls and sticks (label; Osborn & Helmy 1980).

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

D. C. D. Happold

Crocidura roosevelti ROOSEVELT'S SHREW

Fr. Crocidure de Roosevelt; Ger. Roosevelts Spitzmaus

Crocidura roosevelti (Heller, 1910). Smithson. Misc. Coll. 56 (15): 6. Rhino Camp, Lado Enclave, Uganda.

Taxonomy Originally described in the genus *Heliosorex*. Genetic data suggest that this species is not closely related to *C. dolichura* and allies (Quérrouil *et al.* 2005). Clusters preferentially with the Euro-African *C. russula*, secondarily with the European *C. leucodon* and the African *C. obscurior* (Quérrouil *et al.* 2001). Synonyms: none. Chromosome number: not known.

Description Small greyish-brown shrew. Pelage soft and comparatively long; hairs 3–4 mm. Dorsal pelage greyish-brown; hairs grey at base, mid-brown to cinnamon-brown at tip. Ventral pelage whitish-grey, hairs pale grey at base, white at tip. Head similar in colour to dorsal pelage. Ears relatively large. Fore- and hindlimbs flesh-coloured, with sparse covering of short white hairs on upper surface. Hindlimbs relatively long; whitish. Soles of hindfeet with granular surface between plantar pads. Tail relatively very long (ca. 85% of HB to 94% and 96% of HB in Angola), bicoloured, pale brown above, paler below; pilosity ca. 70%. First incisor moderately long and hooked. Third molar narrow to medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Northern, Eastern and Southern Rainforest–Savanna Mosaics of central Africa. Recorded

Crocidura roosevelti

from Central African Republic, DR Congo, Uganda, Rwanda, Tanzania and NE Angola (Hutterer 1981a).

Habitat Margins of forest and savanna (Hutterer 2005b).

Abundance Uncertain. Only recorded from a few localities within the geographical range.

Remarks Recorded occasionally in pellets of Barn Owls *Tyto alba* in Garamba N. P., DR Congo (5 of 172 shrews; 13 spp.) (Heim der Balsac & Verschuren 1968).

Conservation IUCN Category: Least Concern.

Crocidura russula GREATER SHREW (GREATER WHITE-TOOTHED SHREW)

Fr. Crocidure musette; Ger. Große Weißzahnschnecke

Crocidura russula (Hermann, 1780). In: Zimmermann, Geogr. Gesch. Mensch. Vierf. Tiere 2: 382. Near Strasbourg, Bas Rhin, France.

Taxonomy Originally described in the genus *Sorex*. Although two subspecies are recognized here, molecular data has provided evidence that populations of this species in Tunisia may represent a separate species, *C. ichneusi* (listed as such in Hutterer 2005b), within the 'russula group', separate from populations in Morocco (Vogel *et al.* 2004, Cosson *et al.* 2005). Synonyms (Africa only): *chaouiensis*, *foucauldi*, *heljanensis*, *yebalensis* (see Hutterer 2005b for non-African synonyms and comment). Subspecies: two. Chromosome number: 2n = 42, FN = 60 in Morocco (Catzefflis *et al.* 1985, Vogel *et al.* 1992), aFN = 68 in Tunisia (Sarà & Zanca 1992).

Description Small to small-medium shrew. Pelage soft and moderately dense; hairs ca. 4 mm. Dorsal pelage greyish-brown to reddish-brown; hairs dark grey at base, reddish-brown at tip. Flanks similar in colour to dorsal pelage, or paler and greyer. Ventral pelage grey to whitish-grey, sometimes tinged with russet; hairs grey at base, off-white or russet at tip. Ears relatively large, not concealed by pelage. Hindfeet dark on dorsal surface. Tail of medium relative length (ca. 50% of HB), dark brown; pilosity 60%. Skull elongated, rostrum narrow. Third unicuspid tooth relatively large, even larger than the second, and larger than the adjacent cusp (parastyle) of the fourth upper premolar. Parastyle of the fourth upper premolar poorly developed, standing off the metacone. Mandible length and height of coronoid process (see Measurements) are useful distinguishing characters. Nipples: not known.

Geographic Variation A stepped cline, with changes in shape and size, and in chromosome characteristics, occurs from the eastern to the western Maghreb (Sarà & Vogel 1996). Although recognized as two subspecies, Vogel *et al.* (2004) and Cosson *et al.* (2005) suggest each subspecies represents a species:

C. r. russula: Morocco; western part of geographic range (the 'modern' part of range) including the form *yebalensis*.

C. r. ichneusi: Tunisia; eastern part of range (the 'ancient' part of the range) (Brändli *et al.* 2005, Hutterer 2005b).

Distribution Mediterranean Coastal BZ. Recorded from Morocco, Algeria and Tunisia north of the Atlas Mts, from sea level up to at least 2800 m (Hutterer 1986e, Vogel & Maddalena 1987, Kowalski & Rzebik-Kowalska 1991). Extraliminally widespread in S and W Europe, including some Mediterranean islands.

Habitat Semi-open grasslands, cultivated areas and gardens (sheltering mainly in hedgerows and dry stone walls between the fields), low shrubs, halophyte vegetation of estuaries and matorrals. All habitats are characterized by being quite humid and covered with vegetation.

Crocidura russula

Abundance Quite common and widely distributed. Populations may attain high densities; fluctuations in density are probably related to rainfall.

Adaptations Active day and night with peaks of activity after dusk and around dawn. Activity periods are longer during night than day, and vary according to climate (Genoud & Vogel 1981).

Foraging and Food Mainly insectivorous. Principal prey includes insects, snails and earthworms. Occasionally eats small vertebrates such as lizards and young rodents. Daily energetic expenditure requires a food intake of ca. 50% of body weight/day (Genoud 1985, Churchfield 1990).

Social and Reproductive Behaviour Territorial in summer during the reproductive season, but may live in small groups during winter.

Reproduction and Population Structure Reproduction occurs from Feb to Nov in the Mediterranean regions of Europe, and peaks of reproductive activity occurs in late spring to early summer. Gestation: 28–33 days. Litter-size: 1–6 (mean: 3.5–4.6 in Europe). Weaned at Day 18–20 (Genoud & Vogel 1991). Age at first breeding: ca. 3 months. Maximal longevity: 1–1.5 years. Females may have up to eight litters (4–5 in a single breeding season). Dispersal of young is highly female-biased (Favre *et al.* 1997). Males may pair simultaneously with up to four ♀♀, and ♀♀ paired with multiple-mated ♂♂ wean significantly more offspring (Bouteiller & Perrin 2000); consequently a high level of genetic diversity can be observed in subpopulations.

Predators, Parasites and Diseases Regular prey of Barn Owls

Tyto alba in N Morocco, forming ca. 2% to 22% of the diet (Aulagnier *et al.* 1999) and of Tawny Owls *Strix aluco* in Boukhalfa (Algeria), forming up to 13.9% of the diet (Hamdine *et al.* 1999). Occasional prey of the Pharaoh Eagle-owl *Bubo ascalaphus* and the Marsh Owl *Asio capensis*. Ectoparasites include *Nosopsyllus barbarus* (Siphonaptera, Leptopsyllidae) (Hastriter & Tipton 1975).

Conservation IUCN Category: Least Concern.

Because of its synanthropic habits, this shrew can suffer from the use of insecticides and other toxic chemicals.

Stéphane Aulagnier & Peter Vogel

Crociodura selina UGANDAN LOWLAND SHREW

Fr. Crociodure de forêt d'Ouganda; Ger. Uganda-Tieflandspitzmaus

Crociodura selina Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 371–372. Chagwe, Mabira Forest, Uganda.

Taxonomy Previously included in *C. fumosa* or *C. luna*, but considered a distinct species by Dippenaar & Meester (1989). Synonyms: none. Chromosome number: not known.

Description Medium-sized shrew. Dorsal pelage dark brownish-grey to slate-grey. Ventral pelage slightly paler. Feet reddish-brown to yellowish-brown. Tail dark reddish-brown above, slightly paler below. Tail relatively long (ca. 70% of HB); pilosity 68–78%. Skull with a proportionally wide interorbital region (4.8 [4.7–5.0] mm, n = 5), moderately robust rostrum, narrow and flat braincase, robust unicusps and moderately wide M³ (Dippenaar & Meester 1989). Nipples: not known.

Geographic Variation A newly discovered population in SE Kenya (Oguge *et al.* 2004) may be slightly larger and requires detailed comparison with the Uganda populations.

Distribution Endemic to Africa. Isolated records in Uganda (Mabira Forest, Kibanda Forest, Mbanga Forest) and SE Kenya (Kyulu Hills).

Habitat Lowland evergreen forest in Uganda (Mabira, Kibanda and Mbanga Forests). In Kenya (Kyulu Hills) the species was found at 1700 m in mist forest consisting primarily of the plants *Alangium chinense*, *Ilex mitis*, *Ficus* spp., *Xymalos* sp., *Neuboutonia* sp., *Schefflera* sp., *Prunus africana*, *Olea capensis* and *Rapanae* sp. (Oguge *et al.* 2004).

Abundance In Uganda, the species is known from only a few specimens collected in three different forests; no population study has been conducted so far. In Kenya (Kyulu Forest), *C. selina* occurs in reasonably high numbers (63% of all shrew captures), together with *C. luna* and *C. hildegardeae* (Oguge *et al.* 2004).

Remarks A medium-sized terrestrial shrew; no other available information.

Conservation IUCN Category: Data Deficient (previously Endangered).

Crocidura selina

Crocidura silacea LESSER GREY-BROWN SHREW (LESSER GREY-BROWN MUSK SHREW)

Fr. Crocidure grisâtre; Ger. Kleine graubraune Moschusspitzmaus

Crocidura silacea Thomas, 1895. Ann. Mag. Nat. Hist., ser. 6, 16: 53. Figtree Creek, De Kaap, Barberton district, Mpumalanga Province, South Africa.

Taxonomy Monotypic. Although described as a valid species, there has been some doubt in the literature about the status of *silacea*. Meester (1963) considered it to be a monotypic species, Heim de Balsac & Meester (1977) referred to it as a subspecies of *C. gracilipes*, Smithers (1971) listed it as a synonym of *Crocidura cyanea infumata* while Meester *et al.* (1986) reverted to the original designation of *C. silacea*. Morphometric studies by Meester *et al.* (1985), Taylor *et al.* (1994) and Taylor & Contrafatto (1996) support its status as a valid species. Synonyms: *holobrunneus*. Subspecies: none. Chromosome number: not known.

Description Small to small-medium shrew. Dorsal pelage buffy-brown to brown grizzled with pale grey or fawn; hairs slaty-grey at base, pale grey to fawn subterminal band, brown at tip. Ventral pelage pale grey with brown tinge; hairs slaty-grey at base, pale grey or fawn at tip. Colours of dorsal and ventral pelage merge gradually on flanks. Summer pelage is darker than winter pelage. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet brown. Tail relatively long (ca. 70% of HB), pale to dark brown above, paler below; pilosity not known. Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezian Woodland BZ and Highveld BZ. Recorded from Zimbabwe, N Botswana, South Africa (North West, Northern, Gauteng, Mpumalanga and KwaZulu–Natal

Provinces), Swaziland and S Mozambique (Wolsan & Hutterer 1998) in areas with rainfall exceeding 500 mm/year (Meester 1963). Because of uncertainty over the taxonomic status of the species, its geographical range possibly also includes Angola, S Zambia and

Crocidura silacea

S Malawi to Kenya and Uganda (Meester *et al.* 1986). Geographic limits uncertain.

Habitat Montane forest and grassland, coastal forest, savanna woodland, bush, grassland and even rocky habitats (Meester 1963, Rautenbach 1982, Skinner & Smithers 1990). Wide habitat tolerance.

Abundance Uncommon; seldom collected.

Adaptations A physiological trial on a single specimen produced an average daily metabolic rate slightly lower than expected for a crocidurine of its size (R. M. Baxter unpubl.).

Foraging and Food No detailed information; presumably insectivorous.

Social and Reproductive Behaviour Vocalizations include an occasional short, strident squeak during aggressive encounters. A similar squeak is given when alarmed. Digging and rooting has rarely been observed in captivity. Nests are spherical with 2–4 entrances.

Reproduction and Population Structure No information.

Predators, Parasites and Diseases Remains of the species have been recovered from pellets of Barn Owls *Tyto alba* (Vernon 1972). Domestic cats also prey on these shrews (Meester 1963).

Conservation IUCN Category: Least Concern.

Crocidura smithii DESERT SHREW (DESERT MUSK SHREW)

Fr. Crocidure de Smith; Ger. Wüsten-Moschusspitzmaus

Crocidura smithii Thomas, 1895. Ann. Mag. Nat. Hist., ser. 6, 15: 51. Finik, Webi Shebeli, Ethiopia.

Taxonomy Specimens reported from Somalia by Heim de Balsac (1966) represent *C. macarthuri*. The widespread disjunct distribution (see below) may indicate that the two populations represent different species (Hutterer 1986a). Synonyms: *debalsaci*. Subspecies: none. Chromosome number: not known.

Description Small–medium shrew. Dorsal pelage slate-grey to pale yellowish-brown; hairs grey at base. Ventral pelage white; hairs grey at base, white at tip. Clear delineation between colours of dorsal and ventral pelage rather high up on the flanks; including almost to the top of the ears and the cheeks. Ears naked, sticking out from side of body. Fore- and hindlimbs white; hindfeet short. Tail of medium relative length (ca. 54% of HB), white, thick at base; pilosity ca. 100%. Nipples: not known.

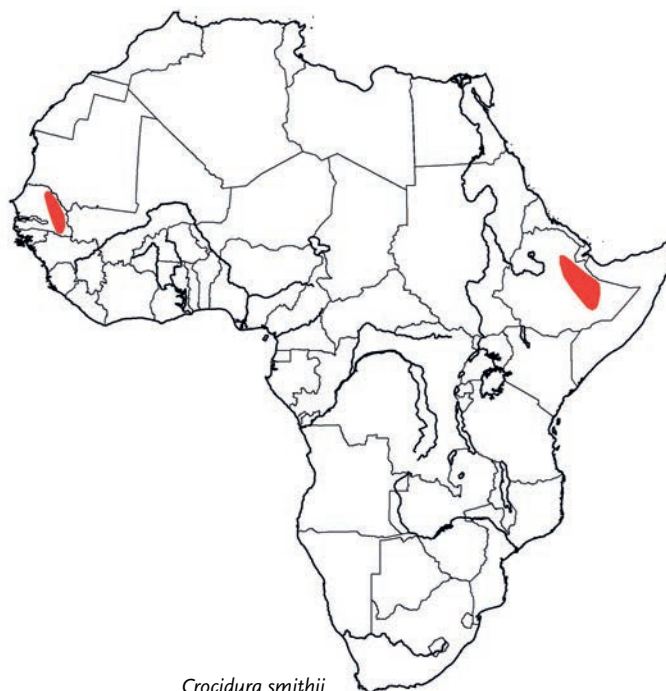

Geographic Variation The form *debalsaci* from Senegal (described as a subspecies – see Hutterer 1981b – but now considered as a synonym) is larger in size than specimens from Ethiopia.

Distribution Endemic to Africa. Sudan Savanna BZ (Senegal) and Somalia–Masai Bushland BZ (Ethiopia). Recorded only from lowland Ethiopia and Senegal, but not recorded from any locality between these countries

Habitat Not known. One specimen found in a termitarium in Senegal (Hutterer 1981b).

Abundance Very rare; known only by a few specimens.

Remarks Apparently no other information available.

Crocidura smithii

Conservation IUCN Category: Least Concern.

Crocidura somalica SOMALI SHREW

Fr. Crocidure de Somalie; Ger. Somalia-Spitzmaus

Crocidura somalica Thomas, 1895. Ann. Mag. Nat. Hist., ser. 6, 16: 52. Middle Webi Shebeli (about 05° 30' N, 44° 00' E) near Geledi (Galadi), Ethiopia.

Taxonomy Revised by Hutterer & Jenkins (1983). Similar to *C. yankariensis* but relationships unknown. The subspecies *dhofarensis* (Hutterer & Harrison 1988, Harrison & Bates 1991) from Oman is now considered to be a separate species (Hutterer *et al.* 1992a, Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Small–medium shrew. Dorsal hairs 3–4 mm in length. Dorsal pelage slaty-grey, more or less variegated with brown. Ventral pelage clearly grey. Chin white. Ears whitish, very finely haired. Fore- and hindfeet white. Tail relatively long (ca. 66% of HB), slender, slightly thicker at base; pale brown above, white below, bristles white (partly quoted from Thomas 1895); pilosity ca. 80%. Skull small and slender (figured in Hutterer & Jenkins 1983); dorsal profile straight, slopes gradually upwards from rostrum to back of braincase; rostrum relatively long and slender; zygomatic process subangular, aligned with paracone of M² region gradually increasing in width from anterior to posterior; braincase suboval in dorsal view. Coronoid process of mandible medium in height and width. Dentition as in other crocidurines, lacks special features. I¹ short; M³ medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sudan Savanna BZ and Somalia–Masai Bushland BZ. Recorded from three localities in Ethiopia (Hutterer 1980, Demeter 1982), and in Sudan (Kordofan Province; Hutterer & Kock 1983) and Mali (Hutterer *et al.* 1992a). Probably also in Somalia (Hutterer 2005b). The locality of the holotype, ‘Webi Shebeli, Somaliland’, is in fact in Ethiopia near the border with Somalia (see Moreau *et al.* 1946).

Habitat Dry savanna and semi-desert. Granite rocks and sandy valleys in the Adrar de Iforas (Mali) (Dobigny *et al.* 2001).

Abundance Uncertain. An owl pellet assemblage from Kordofan, Sudan, contained four specimens (= 3.4%) among 123 shrews of five species (Hutterer & Kock 1983). Also present in small numbers in another assemblage from Adrar de Iforas, Mali (Dobigny *et al.* 2001).

Remarks Skull remains have been found in pellets of Spotted Eagle-owls *Bubo africanus* in Awash N. P., Ethiopia (Demeter 1982), and in pellets of Barn Owls *Tyto alba* in Kordofan, Sudan (Hutterer & Kock 1983) and in Adrar de Iforas, Mali (Dobigny *et al.* 2001). Two individuals were found drowned in a calabash full of milk in the desert of NE Mali (Hutterer *et al.* 1992a). *Crocidura yankariensis* – a similarly small species – coexists with *C. somalica* in Sudan and Ethiopia; *C. yankariensis* differs by having a densely haired tail, short hindfoot (9–10 mm), larger ears, lower part of hindlimb (tibia) without long body hairs (figured in Hutterer & Jenkins 1983), and a more rectangular skull with heavier dentition.

Conservation IUCN Category: Least Concern.

Crocidura stenocephala **KAHUZI SWAMP SHREW**

Fr. Crocidure du Mont Kahuzi; Ger. Kahuzi Sumpfspitzmaus

Crocidura stenocephala Heim de Balsac, 1979. Säugetierk. Mitt. 27: 258. Kahuzi-Biega National Park, E DR Congo.

Taxonomy Described as a subspecies of *C. littoralis* but regarded as a full species by Hutterer (1982, 2005a). Synonyms: none. Chromosome number: not known.

Description Large shrew. Dorsal pelage blackish, superficially brownish; hairs silvery-ash grey at base, brownish at tip. Ventral pelage brownish-grey, sometimes with olive tinge, paler than dorsal pelage; hairs pale grey at base, pale brownish at tip. Undersurface of head and neck ash-grey. Ears covered with short hairs and partly covered by pelage. Hindfeet dark brown, forefeet pale brown. Tail relatively long (ca. 77% of HB), dark brown above, paler below; appears naked but with very short inconspicuous bristles; does not taper towards tip, pilosity <20%. Skull similar to that of *C. littoralis*, but clearly narrower; cutting edge of mandibular incisors with two denticles. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ, in regions around the Albertine Rift Valley in E DR Congo and SW Uganda. Recorded from only three montane swamps (2100–2300 m) at the foot of Mt Kahuzi, E DR Congo (Dieterlen & Heim de Balsac 1979) and in Bwindi Impenetrable N. P., SW Uganda (Kasangaki *et al.* 2003).

Habitat Swamps dominated by *Cyperus latifolius* (E DR Congo). Water in the swamps is normally slightly above ground level, but covered by a thick layer of floating plants, which provide shelter and nesting facilities (see also below).

Abundance This species (and *C. kivuana*) are often the commonest shrews in some swamps in E DR Congo. In one swamp, there were 14 *C. stenocephala*, one *Sylvisorex megalura*, one *S. granti*, but no *C. kivuana*. In another swamp, there were 19 *C. stenocephala*, 22 *C. kivuana* and seven specimens of four additional species.

Remarks Although there appear to be no special morphological adaptations for living in swamps, it is assumed that these shrews must accommodate to a very moist habitat and changing water levels. Frequently the swamps are flooded and the water level is 20–30 cm above ground level. One pregnant ♀ (out of 13) was found during the wet season (Mar). Sex ratio (captures): 23 ♂♂ to 13 ♀♀ (E DR Congo; F. Dieterlen unpubl.).

Crocidura stenocephala

Conservation IUCN Category: Endangered.

This species is threatened because of its rarity and very restricted geographic range; in this respect it is similar to the other endemic species of the Albertine Rift Valley.

Crocidura tansaniana TANZANIAN SHREW (AMANI MUSK SHREW)

Fr. Crocidure de Tanzanie; Ger. Tansania-Spitzmaus

Crocidura tansaniana Hutterer, 1986. Bonn. Zool. Beitr. 37: 27. Amani, East Usambara Mts, Tanzania.

Taxonomy Considered to be part of the *C. monax-littoralis* species group (Hutterer 1986b). Synonyms: none. Chromosome number: not known.

Description Large stout shrew with dark chocolate-brown pelage. Pelage dense and short (5 mm on back, 4 mm on neck, 4.5 mm ventrally). Dorsal pelage chocolate-brown; hairs silvery-grey with brown tip. Ventral pelage silvery-brown, paler than dorsal pelage; hairs grey with pale brown tip. Colours of dorsal and ventral pelage merge on flanks. Vibrissae long. Ears prominent with very small hairs. Flank gland usually not visible in ♂♂ unless pelage is parted. Fore- and hindfeet paler than dorsal pelage; hindfeet dark on outer edge and paler on inner edge with short silvery hairs on the upper surface. Tail relatively long (60–70% of HB), unicoloured; pilosity ca. 30%. First incisor long and hooked. Third molar medium. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the East Usambara Mts, N Tanzania.

Habitat Undisturbed or slightly disturbed montane forests in the Amani area of the East Usambara Mts where soil is moist. Not recorded in smaller disturbed forest patches in the same area (30 ha or smaller), nor in agricultural areas.

Abundance The most abundant species of shrew recorded in surveys of undisturbed forest in the East Usambara Mts; comprised ca. 50% of shrews collected ($n = 33$). Syntopic with *C. hildegardae*, *C. olivieri* and *Sylvisorex howelli* (Stanley *et al.* 2011).

Remarks Terrestrial and nocturnal. Males tended to outnumber females during three years of sampling (♂ : ♀ ratios were: 2 : 0 [$n = 2$, 1991]; 3 : 1 [$n = 12$, 1992]; 18 : 17 [$n = 35$, 1993]; and 29 : 20 [$n = 49$, 1991–93]). Average testes length 4.5 mm (3–6 mm), average width 2.5 mm (2–4 mm) ($n = 17$, 1991–93). Most of the ♀♀ examined (Jul–Sep 1991–93) were nulliparous and two were pregnant ($n = 13$). Embryo number: two ($n = 2$), one embryo in each horn; crown–rump lengths of the largest embryos: 8 and 14 mm. Ratio of juveniles to adults (based on toothwear) was 11 : 23 in 1993 (Stanley *et al.* 2011).

*Crocidura tansaniana*

Conservation IUCN Category: Endangered.

Measurements*Crocidura tansaniana*HB: 96 (80–110) mm, $n = 42$ T: 68 (58–76) mm, $n = 49$ HF: 17 (15–19) mm, $n = 49$ E: 11 (8–14) mm, $n = 49$ WT: 14.8 (9.5–20) g, $n = 49$ CI: 25.1 (23.8–26.1) mm, $n = 43$ GWS: 10.8 (10.3–11.4) mm, $n = 43$ I¹–M³: 11.1 (10.7–12.0) mm, $n = 43$ East Usambara Mts, Tanzania (Stanley *et al.* 2011)

Crocidura tarella TARELLA SHREW

Fr. Crocidure de Tarella (Crocidure d'Ouganda); Ger. Tarella-Spitzmaus

Crocidura tarella Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 511; ser. 8, 16: 135. Chaya, near Ruchuru, Congo Belge (= near Rutshuru, DR Congo).

Taxonomy Described as a subspecies of *C. turba* (Dollman 1915a, d) and also considered as a subspecies of *C. zaodon* (Heim de Balsac

& Meester 1977); now recognized as a distinct species by Dippenaar (1980b). Synonyms: none. Chromosome number: not known.

Description Large shrew. Dorsal pelage dark reddish-brown. Ventral pelage grey with reddish-brown wash and silvery sheen. Feet dark reddish-brown. Tail relatively long (63% of HB), blackish-brown above, paler below; pilosity 85–90%. Skull: wide interorbital region; wide maxillary region; narrow braincase. Unicuspid broad; third upper molar moderately broad; talonid of third lower molar with entoconid and talonid basin. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Eastern Rainforest–Savanna Mosaic. Recorded from NE DR Congo and Uganda. Distribution disjunct; limits uncertain.

Habitat Forest.

Abundance No information.

Remarks Apparently no other information.

Conservation IUCN Category: Endangered.

Crociodura tarfayensis SAHARAN SHREW (TARFAYA'S SHREW)

Fr. Crocidure de Tarfaya; Ger. Sahara-Spitzmaus

Crociodura tarfayensis Vesmanis and Vesmanis, 1980. Zool. Abh. Mus. Tierk. Dresden 36: 47. 8 km south Tarfaya, Agadir Prov., Morocco.

Taxonomy All related forms described as species or subspecies by Vesmanis & Vesmanis (1980). Relationship with possible conspecific *Crociodura* species from West Africa and Europe needs to be more carefully evaluated. Synonyms: *agadiri*, *gouliminensis*, *tiznitensis*. Subspecies: none. Chromosome number: not known.

Description Small shrew, a little smaller than *C. russula*. Dorsal pelage pale greyish-brown, hairs long (4–6 mm) and smooth. Ventral pelage whitish, sharply contrasting with dorsal pelage. Hindfeet pale on upper surface. Tail of medium relative length (ca. 60% of HB); hairy; pilosity not known. Teeth stronger than those of *C. russula*, sharing some characteristics with those of *C. whitakeri*: third unicuspid tooth smaller than the second unicuspid, and the same size as the adjacent, well-developed cusp (parastyle) of the fourth upper premolar. First and second upper molars short and broad. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sahara Arid BZ. Restricted to the Atlantic coast of Morocco, south of Agadir, and parts of Western

Sahara into Mauritania. The specimens reported as *C. whitakeri* by Heim de Balsac (1948, 1968e) undoubtedly belong to *C. tarfayensis* according to the measurements of Vesmanis (1976). All records of *C. whitakeri* from south of Oued Draa probably represent *C. tarfayensis*.

Habitat Stony and sandy habitats with scarce vegetation, such as bushy steppe with *Euphorbia*, where rainfall is low. Probably also inhabits stone screes (because it is abundant in pellets of rock-dwelling owls) and bare gravel plains. Avoids human habitats.

Abundance Uncertain. May be locally abundant (as suggested by abundance in owl pellets). Population numbers seem to fluctuate depending on the alternation of dry and moister periods. May be declining following recent climate changes, which have reduced its geographic range.

Remarks May comprise a major part (over 30%) of the diet of Barn Owls *Tyto alba* and Pharaoh Eagle-owls *Bubo ascalaphus*, and occasionally of Little Owls *Athene noctua* (Thévenot *et al.* 1988).

Conservation IUCN Category: Data Deficient.

Most of the known specimens were collected some time ago when shrews were apparently more numerous. The recent desertification and northern expansion of the Sahara might cause a serious threat for the survival of this species.

Crocidura telfordi TELFORD'S SHREW

Fr. Crocisure de Telford; Ger. Telfords Spitzmaus

Crocidura telfordi Hutterer, 1986. Bonn. Zool. Beitr. 37: 28. Morningside, Uluguru Mts, Tanzania. 1150 m.

Taxonomy Considered to be part of an endemic group of shrews in the Eastern Arc Mts (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Very large shrew with chocolate-brown pelage. Dorsal pelage chocolate-brown; hairs silvery-grey with brown tips; hairs 5–6 mm on back, 4 mm on neck. Ventral pelage slightly paler brown than dorsal pelage; hairs 3 mm, brown at tip. Vibrissae long. Ears prominent with few hairs. Fore- and hindfeet paler than dorsal pelage. Hindfeet relatively long (17–19% of HB). Tail relatively long (65–85% of HB), slightly bicoloured; pilosity 5%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from montane forests of the Uluguru and Udzungwa Mts, Tanzania.

Habitat Undisturbed or slightly disturbed montane forests where soil is moist. Not recorded in smaller disturbed forest patches in the same area (30 ha or smaller), nor in agricultural areas.

Abundance In samples of shrews from the montane forests of the Uluguru and Udzungwa Mountains, *C. telfordi* was one of the species that was the least well represented. In an elevational survey of the Udzungwa Mts, *C. telfordi* comprised 1% of total shrews sampled

Crocidura telfordi

(n = 145). Other shrews that occurred in this sample include *C. elgonius*, *C. desperata*, *C. hildegardeae*, *C. monax*, *C. olivieri* and *Myosorex kihaulei* (W.T. Stanley unpubl.).

Remarks Terrestrial. Nocturnal and diurnal: two individuals were caught during the night and two were caught during the day ($n = 4$; W.T. Stanley unpubl.). A single adult ♀ collected in Aug–Sep from Udzungwa Mts was not pregnant. One ♂ collected in Aug–Sep from the Uluguru Mts had testes length of 4 mm and width of 3 mm (W.T. Stanley unpubl.).

Conservation IUCN Category: Endangered.

The geographic distribution is fragmented and suitable habitat is declining.

Crocidura thalia THALIA'S SHREW

Fr. Crocidure de Thalia; Ger. Thalias Spitzmaus

Crocidura thalia Dippenaar, 1980. Ann. Transvaal Mus. 32 (6): 138. Gedeb Mts, SE of Dodola, Bale, Ethiopia (ca. 06° 55' N, 39° 10' E). 2600 m.

Taxonomy A member of the endemic Ethiopian *C. glassi* complex (*C. glassi*, *C. lucina*, *C. thalia*, *C. macmillani* and *C. baileyi*) (Dippenaar & Meester 1989). Synonyms: none. Chromosome number: $2n = 36$ (L. Lavrenchenko unpubl.).

Description Medium-sized greyish-brown shrew. Dorsal pelage greyish-brown (west of the Ethiopian Rift Valley) to dark grey with brown to reddish-brown wash (east of the Rift Valley); hairs grey at base, brown or reddish-brown at tip. Ventral pelage pale grey to blackish with ochre wash; hairs grey to dark-grey at base, pale-yellowish to ochre-yellowish at tip. Dorsal surface of fore- and hindfeet brownish, greyish-brown or yellowish-grey. Tail relatively long (ca. 70% of HB), dark brown above, brown below; pilosity 80%. Skull with inflated braincase as is typical for other high altitude Ethiopian *Crocidura*. Nipples: not known.

Geographic Variation Pelage colouration of populations west of the Ethiopian Rift Valley differ in colour from those east of the valley – see above (Dippenaar 1980a).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ, mostly in highland regions in Ethiopia. The most widespread of the endemic shrews of Ethiopia, found both east and west of the Ethiopian Rift Valley, from 515 to 3300 m (Yalden & Lagen 1992). Records currently suggest four separate regions, three in the highlands and one at lower altitude (Baro R., near border with Sudan).

Habitat Open habitats from humid woodland savanna to highland grasslands and scrub. Largely absent from the afromontane forest with a dense canopy where it inhabits only moist riverine habitats (Lavrenchenko 2000).

Abundance Generally uncommon. Comprises 7% of small mammals captured ($n = 88$) in Harennia Forest and neighbouring ericaceous bush; may be rather abundant locally (up to 40% of small mammals on some trapping lines) (L. Lavrenchenko unpubl.)

Crocidura thalia

Remarks Presumed to be nocturnal and insectivorous or omnivorous. In the Bale Mts not known to breed during most of the dry season (no pregnant ♀♀ trapped during Dec–Feb).

Conservation IUCN Category: Least Concern.

Measurements

Crocidura thalia

***Crocidura theresae* THERESE'S SHREW**
 Fr. Crocidure de Thérèse; Ger. Thérèses Spitzmaus

Crocidura theresae Heim de Balsac, 1968. Mammalia 32: 398. Nzerekore, Guinea.

Taxonomy First described as *Crocidura* aff. *foxi*, within the *C. poensis* group (Heim de Balsac 1958), then considered as a valid species (Heim de Balsac 1968a). Morphologically closely related to *C. foxi* and *C. poensis* (Heim de Balsac 1968a), and electrophoretically to *C. poensis* (Maddalena 1990a). Synonyms: none. Chromosome number: 2n = 50 (Côte d'Ivoire; Meylan 1971), FN = 82–86 (Guinea; Maddalena 1990b).

Description Medium to large shrew. Dorsal pelage grey to brown. Ventral pelage paler, exceptionally whitish. No clear delineation between colours of dorsal and ventral pelage on flanks. Fore- and hindfeet brown. Tail medium to long (52% [39–62%] of HB), thickset, with sparse brown hairs; pilosity ca. 75%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Guinea Savanna BZ. Recorded from Sierra Leone and Guinea to Ghana.

Habitat All types of grasslands up to 1600 m, and also ricefields (Heim de Balsac 1968a).

Abundance Locally abundant; hundreds trapped in savannas at Dabou, Côte d'Ivoire (L. Bellier, in Heim de Balsac 1968a). In Ziamia Biosphere Reserve, Guinea, common in fields (16.2%, n = 272 shrews, 9 spp.), but extremely rare in all other habitats (primary–secondary forest, old fallow land and forest plantations) (P. Barrière unpubl.).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

***Crocidura turba* TURBO SHREW**
 Fr. Crocidure de Chilui; Ger. Turbo-Spitzmaus

Crocidura turba Dollman, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 176. 'Chilui Island, Lake Bangweolo' (= Chilubi I., Zambia).

Taxonomy Aggundey & Schlitter (1986) list this species as *C. zaodon* with four subspecies (*zaodon*, *provocax*, *lakiundae* and *kempi*). The species has been confused with *zaodon* (now placed as a synonym

of *C. nigrofusca*) (Hutterer 2005b). Synonyms: *angolae*. Subspecies: none. Chromosome number: not known.

Description Large to very large shrew with short soft pelage. Dorsal pelage blackish-brown or dark-brown; hairs grey at base, dark brown at tip. Ventral pelage grey with a brownish tinge medially, shorter than on dorsal surface or flanks. Throat pale or ashy-grey. Head narrow, with long muzzle with sparkling bright brown vibrissae that appear darker at base. Nose with a conspicuous blob on tip. Pinnae oval, slanting posteriorly towards shoulders; slightly paler than dorsal pelage. Limbs small. Each digit with small straight sharp pointed claw. Tail of medium relative length (ca. 58% of HB), brown; pilosity ca. 75%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Widely distributed. Forest–savanna mosaics and Zambezan Woodland BZ. Recorded from NW Cameroon to Kenya, and southwards to Zambia and Angola. Limits of distribution uncertain. In Zambia, probably limited to areas that have a rainfall of at least 900 mm/year, so not present in low-lying valleys (Ansell 1978).

Habitat Dry forests, montane forests, riverine habitats, bushlands and grasslands.

Abundance Locally common. In Kenya, locally uncommon but widely distributed.

Remarks A ♂ captured in mid-dry season (Jan) in Ololua Forest, Kenya, was in reproductive condition.

Conservation IUCN Category: Least Concern.

Despite loss of many suitable habitats in Kenya where the species occurs, it is probably not under threat at the present time as some of its habitats are in protected areas.

Crocidura ultima ULTIMATE SHREW

Fr. Crocidure de Nyeri; Ger. Ultimative Spitzmaus

Crocidura ultima Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 517. 1916. Ann. Mag. Nat. Hist., ser. 8, 17: 204. Jombeni Range, Nyeri District, Kenya. 1424 m.

Taxonomy Placed as a synonym of *C. monax* by Heim de Balsac & Meester (1977) but considered to be a distinct species within the *littoralis*–*monax* group by Dippenaar (1980b). Known only from the holotype. Synonyms: none. Chromosome number: not known.

Description Large shrew. Dorsal pelage reddish-brown mottled with grey. Ventral pelage greyer, not clearly delineated from the brownish colour of the flanks. Upper surface of fore- and hindfeet pale buffish-brown. Claws of hindfeet slightly larger than those of forefeet. Tail relatively long (ca. 70% of HB), reddish-brown above and below, covered with very short brownish hairs; pilosity ca. 20%.

Skull broad with a rather blunt muzzle. Teeth small; second upper unicuspid conspicuously smaller than (and overlapped by) third unicuspid, circular in section with well-developed cingula. Third upper molar broad, entoconid present on talonid of third lower molar. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the Jombeni Range near Nyeri, Kenya.

*Crocidura ultima*

Habitat No information; type locality suggests habitat may be montane forest.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.
Previously assessed as Critically Endangered.

Crocidura usambarae USAMBARA SHREW

Fr. Crocidure des Monts d'Usambara; Ger. Usambara-Spitzmaus

Crocidura usambarae Dippenaar, 1980. Ann. Transvaal Mus. 32: 128. Shume, 16 miles N of Lushoto, West Usambara Mts, Tanzania.

Taxonomy Dippenaar (1980a) suggested that *C. usambarae* is related to *C. monax*. Synonyms: none. Chromosome number: not known.

Description Medium-sized reddish-brown shrew. Dorsal hairs ca. 6 mm on back, ventral hairs 4 mm. Dorsal pelage reddish-brown; hairs slate-grey at base, reddish-brown on terminal quarter. Ventral pelage pale reddish-brown (paler than dorsal pelage); hairs slate-grey at base (ca. 60–75% of the hair), yellowish-white subterminal band, pale reddish-brown at tip. Fore- and hindfeet reddish-brown, with long hairs on upper surface. Tail relatively long (ca. 70% of HB), dark above, slightly paler below; pilosity 10–20% (hairs black). Males on average larger than ♀♀ (Stanley *et al.* 1996a). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. In N Tanzania, recorded from the South Pare (Stanley *et al.* 1996a), West Usambara Mts (Dippenaar 1980a, Howell & Jenkins 1984), and East Usambara Mts (Stanley *et al.* 2011). One specimen (skin only) from the Poroto Mts, S Tanzania, has been tentatively identified as *C. usambarae* (Dippenaar 1980a).

Habitat Moist montane forest and adjacent habitats. One specimen found in an agricultural field adjacent to montane forest in the South Pare Mts (Stanley *et al.* 1996a). Howell & Jenkins (1984)

*Crocidura usambarae*

recorded a specimen from the edge of montane forest, and another in disturbed montane forest in the West Usambara Mts.

Abundance In Chome F. R. South Pare Mts, comprised 70% of all shrews sampled ($n = 10$) at 2000 m, but only 8% of all shrews sampled ($n = 37$) at 1100 m (Stanley *et al.* 1996a).

Remarks In Chome F.R., ♂ : ♀ ratio was 1 : 2 ($n = 3$) at 1100 m, and 6 : 1 ($n = 7$) at 2000 m (Stanley *et al.* 1996a). Of the three ♀♀ in these samples (collected Jul–Sep), two were nulliparous, the third was pregnant. Embryo number: 5 ($n = 1$); three embryos in left uterine horn, two in right horn; crown–rump length of largest embryo 6 mm. One pregnant ♀ from West Usambara Mts in Jan 1981 contained two embryos (one in each horn; maximum crown–rump length 8 mm) (Howell & Jenkins 1984).

Conservation IUCN Category: Endangered.

The distribution is fragmented and suitable habitat is declining.

Crocidura viaria SAVANNA PATH SHREW

Fr. Crocidure de savanna sèche; Ger. Savannen-Wegspitzmaus

Crocidura viaria (I. Geoffroy, 1834). In: Zool. Voy. de Belanger Indes-Orient., p. 127. 'Senegal'.

(Restricted to region between Dakar and St Luis by Hutterer 1984.)

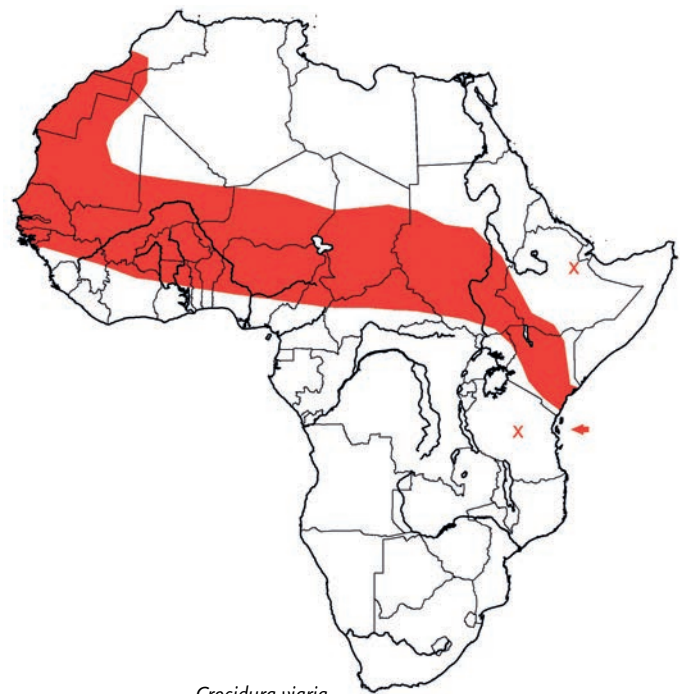

Taxonomy Originally described as *Sorex viarius* (see Hutterer 1983c for details). Member of the *flavescens* species-group (Maddalena 1990a). Synonyms: *bolivari*, *hindei*, *suahelae*, *tamrinensis*. Subspecies: none. Chromosome number: $2n = 50$, $FN = 66$ (Maddalena & Ruedi 1994).

Description Large pale-coloured shrew. Pelage dense, soft, with silky sheen; dorsal hairs 5 mm. Dorsal pelage pale medium brown, with a mottled appearance; hairs dark grey on basal half, pale brown on terminal half, medium brown at tip. Ventral pelage medium reddish-brown or creamy-grey; hairs grey on basal two-thirds, creamy-grey on terminal third. Head similar in colour to dorsal pelage. Ears pale brown, conspicuous, not concealed by pelage. Chin, throat and chest medium reddish-brown (see also below). Fore- and hindfeet pale, slightly pinkish, covered with creamy short hairs. Tail relatively long (ca. 70% of HB), medium brown, slightly paler below; thick at base, tapering to tip; pilosity 75–90%. Braincase flat and broad. First upper incisor long and hooked. Third upper molar medium to wide. Nipples: not known.

Geographic Variation In Morocco, pelage colour of chin and throat same as ventral pelage ($n = 3$); in Senegal, chin and throat have irregular reddish-ginger patches of longer hair ($n = 3$).

Distribution Endemic to Africa. Sahara Arid BZ (in the west of the continent), Sahel Savanna, Sudan Savanna and parts of Guinea Savanna BZs. Recorded from S Morocco to Senegal and eastwards to Sudan, W Ethiopia and Kenya.

Habitat In S Morocco, most numerous in cultivated fields (e.g. lucerne) and dense scrubby vegetation (which is sometimes

Crocidura viaria

inundated) beside seasonal rivers. Also recorded on vegetated sand dunes, and on dunes with thick cover of *Chenopodium murale* or *Euphorbes cactoides* (and boulders).

Abundance Common in certain habitats. In S Morocco, comprised 75% of all small mammals ($n = 8$, 1 sp. of shrew, 2 spp.

of rodent) in dense scrubby vegetation, and 70% in cultivated fields (n = 7, 1 sp. shrew, 1 sp. rodent) (Vogel *et al.* 2000).

Remarks Strictly nocturnal. In Morocco, may use abandoned burrows of rodents for shelter. A specimen from Nigeria was found in owl pellets (Hutterer & Happold 1983).

Conservation IUCN Category: Least Concern.

Measurements

Crocidura viaria

Crocidura virgata MAMFE SHREW

Fr. Crocidure de Mamfe; Ger. Mamfe-Spitzmaus

Crocidura virgata Sanderson, 1940. Trans. Zool. Soc. Lond. 24: 682. Tinta, Assumbo, Mamfe, Cameroon. 2300 ft (06° 15' N, 09° 31' E).

Taxonomy Originally described as a subspecies of *C. occidentalis* (now a synonym of *C. oliveri*). Formerly allocated as a subspecies to *C. gracilipes* (Heim de Balsac & Meester 1977), a species now considered as of uncertain status and restricted to Mt Kilimanjaro; and later included in *C. hildegardae* (Hutterer 1993). Now considered a valid species (Hutterer 2005b) on the basis of different karyotype from *C. hildegardae* (2n = 52, FN = 76) and differences in skull size and shape (Heim de Balsac 1968d). Synonyms: *vulcani*. Subspecies: none. Chromosome number: 2n = 52, FN = 86 (Meylan & Vogel 1982).

Description Small shrew. Dorsal pelage and tail pale chocolate-brown. Ventral pelage gradually changing into greyish-brown. Fleishy parts paler pinkish-grey. Tail relatively long (65% of HB); pilosity 80%. Hindfeet short; metatarsal joint well covered with hairs. Skull similar to that of *C. hildegardae*, but slightly smaller, with shorter and more slender rostrum. I¹ small; M³ large. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Restricted to E Nigeria (Meylan & Vogel, 1982), Tinta in the Mamfe highlands of W Cameroon (Sanderson 1940), Bibundi near Mt Cameroon (*vulcani*; 1500–1600 m; Heim de Balsac 1957b), and Mt Kupé, Cameroon (Heim de Balsac 1968d). Limits of distribution unknown.

Habitat False mountain grass; dry habitat (Sanderson 1940), open forest at 850 m at foot of Mt Kupé (Eisentraut 1973a), and in the crater of Bibundi on Mt Cameroon (Heim de Balsac 1957b).

Abundance No information.

Remarks Meylan & Vogel (1982) reported on a karyotype of a specimen from Okpuje, Nigeria, under the name *Crocidura* cf. *gracilipes*, a name used by Heim de Balsac & Meester (1977) for the *C. hildegardae* group.

Conservation IUCN Category: Data Deficient.

Crocidura voi VOI SHREW

Fr. Crocidure de Voi; Ger. Voi-Spitzmaus

Crocidura voi Osgood, 1910. Field Mus. Nat. Hist. Publ., Zool. Ser. 10: 18. Voi, British East Africa (= Kenya).

Taxonomy Synonyms: *aridula*, *butleri*, *percivali*. Subspecies: none. Chromosome number: not known.

Description Small-medium to medium-sized shrew. Dorsal pelage cinnamon to greyish-brown; hairs grey at base, cinnamon at tip. Ventral pelage and flanks yellowish-grey to greyish-white; hairs grey at base, creamy-yellow at tip. Tail of medium relative length (ca. 45–55% of HB), broad, pale and usually bicoloured; pilosity ca. 100%. Skull: hour-glass shaped, broad and flat. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Sudan Savanna and Somalia–Masai Bushland BZs. Recorded from Mali, N Nigeria, Sudan, Ethiopia, Somalia and Kenya. Distribution disjunct.

Habitat No information. Not obtained during an extensive survey (302 shrews, 12 spp.) in ‘montane forests’ (Shimba Hills, Taita Hills and Kyulu Hills) in SE Kenya, not far from the type locality at Voi (Oguge *et al.* 2004).

Abundance Probably rare; known only from a few specimens at each locality where captured.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Crocidura whitakeri WHITAKER'S SHREW (LESSER MAGHREBI SHREW)

Fr. Crocidure de Whitaker; Ger. Whitakers Spitzmaus

Crocidura whitakeri de Winton, 1898. Proc. Zool. Soc. Lond. 1897: 954. Sierzet, between Marrakech and Essaouira, Morocco.

Taxonomy Described as a subspecies of *C. suaveolens*, but now considered as a valid species. Despite description of several local forms, no consistent geographical variation is currently recognized. Synonyms: *essaouiranensis*, *matruhensis*, *mesatanensis*, *zaianensis*. Subspecies: none. Chromosome number: not known.

Description Small pale shrew, smaller than *C. russula*, with a comparatively larger head and ears. Pelage short (3–4 mm on back). Dorsal pelage short and silky, buffy-brown flecked with white (speckled in the holotype); hairs ash-grey at base with subterminal

band of white, and brownish tip. Ventral pelage whitish; hairs grey on basal half, white on terminal half. Fore- and hindfeet pale or white on upper and lower surfaces. Tail of medium relative length (ca. 50% of HB), pale above, whitish below; pilosity up to 100%. Skull relatively flat with short rostrum. Third upper unicuspid tooth smaller than the second unicuspid, and about the same size as the adjacent, well developed and attached cusp (parastyle) of the fourth upper premolar. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded in the Atlantic and Mediterranean parts of Morocco, Algeria and Tunisia, from sea level to 1800 m. Particularly widely distributed on the Atlantic coast of Morocco, but absent from most of the coastal zone of Algeria where its distribution is along the southern border of the Saharan Atlas. One record (previously listed as *C. suaveolens matruhensis*) from the coastal area of Egypt (Hutterer 1994). May occur in suitable habitats all along the North African coast from NW Africa to Egypt (Hutterer 1994).

Habitat Dry and stony habitats, with sparse vegetation (i.e. steppe or semi-deserts); also sandy coastal dunes. Shelters among rocks as well as in rodent burrows. In Egypt (Setzer 1960, as *C. suaveolens matruhensis*), recorded from 'burrows of the fat sand rat, *Psammomys obesus*, in damp saline depressions just behind the sea' (see also Osborn & Helmy 1980).

Abundance Highest densities recorded in the Atlantic part of Morocco. Common in owl pellets in semi-arid regions of Algeria, but not in the Sahara Desert (Kowalski & Rzebik-Kowalska 1991).

Remarks Mainly nocturnal. Represented 2.1% of the diet of Barn Owls *Tyto alba* in N Morocco, and up to 9.8% in one locality (Aulagnier *et al.* 1999). Also preyed on by Tawny Owls *Strix aluco*, Pharaoh Eagle-owls *Bubo ascalaphus* and Black-winged Kites *Elanus caeruleus*.

Conservation IUCN Category: Least Concern.

Can be adversely affected by pesticides massively used against locusts in the southern part of its range.

Crocidura wimmeri WIMMER'S SHREW

Fr. Crocidure de Wimmer; Ger. Wimmers Spitzmaus

Crocidura wimmeri Heim de Balsac and Aellen, 1958. Rev. Suisse Zool. 65: 952. Adiopodoumé, S Côte d'Ivoire.

Taxonomy Resembles *C. nimbae*, *C. foxi* and *C. nigeriae* in appearance and cranio-dental characteristics, but differs in details of the skull and teeth. Records of this species from Cameroon and Gabon (Brosset 1988) refer to *C. batesi* (Hutterer 2005b). Synonyms: none. Chromosome number: 2n = 50, FN = 84 (Meylan & Vogel 1982).

Description Medium-sized species. Dorsal pelage dark ash-grey to brown. Ventral pelage paler. Tail relatively long (ca. 75% of HB), not densely haired; pilosity not known. Skull elongated, facial region well developed and maxillary region broad (see Heim de Balsac & Aellen 1958 for details). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (Western Region [Ghanian sub-region]). Known only from around Adiopodoumé near Abidjan, S Côte d'Ivoire (Heim de Balsac & Aellen 1958, Vogel 1976).

Habitat Wet, swampy forest near the coast (Heim de Balsac & Aellen 1958).

Abundance Rare and localized.

Remarks Nocturnal. In captivity, mean total activity was 340 min/24 h in 22 phases; 6–45 min/h at night but for only 0–4 min/h during the day (Vogel *et al.* 1981). Energy consumption in captivity was 1.9 kJ/g/h for an individual weighing 23.5 g (Vogel 1976). Can be distinguished from several other African *Crocidura* by its distinctive

defence calls; calls last an average of 217 msec with a frequency of 11.7–15.0 kHz (Hutterer & Vogel 1977).

Conservation IUCN Category: Critically Endangered.

Crocidura wimmeri

Crocidura xantippe XANTHIPPE'S SHREW (YELLOW-FOOTED SHREW)

Fr. Crocidure à pieds jaunes; Ger. Xantippes Spitzmaus

Crocidura xantippe Osgood, 1910. Field Mus. Nat. Hist. Publ., Zool. Ser. 10: 19. Voi, Kenya.

Taxonomy Status uncertain, but probably related to *C. hirta* (Hutterer 1993, 2005a). Synonyms: none. Chromosome number: not known.

Description Large species. Dorsal pelage pale brown with a fine speckling of paler colour; hairs slate-grey, some tipped with brown (resulting in a speckled pattern). Pelage short; hairs 3.6 mm on shoulders, 3.3 mm on chest, 3.7 mm on rump. Ventral pelage whitish-grey with yellowish wash along the ventral mid-line, narrow on neck and wider on chest and abdomen; hairs greyish-white or grey on basal half, yellowish-white on distal half. Ears prominent. Forefeet pale brown to yellowish-brown; hindfeet paler than forefeet. Tail relatively long (ca. 66% of HB), slightly bicoloured, whitish-grey below turning browner on distal third; pilosity 75%. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from SE Kenya and NE Tanzania (Heim de Balsac & Meester 1977, Aggundey & Schlitter 1986). Identification of a specimen in N Kenya (near L. Turkana) is uncertain.

Habitat The holotype was collected in dry thorn scrub habitat in Kenya. Three specimens from the West Usambara Mts came from a variety of habitats at 1100–1300 m, including slightly disturbed montane forest and a *Eucalyptus* plantation (Stanley *et al.* 2011).

Crocidura xantippe

Abundance Uncertain; probably rare. Comprised 1.5% of shrews captured in the West Usambara Mts (n = 53) (W. T. Stanley unpubl.), but not encountered amongst 303 shrews (10 spp.) obtained

in montane forests of SE Kenya within the area of distribution of this species (Oguge *et al.* 2004).

Remarks One ♀ (of three) lactating in Jul (West Usambara Mts; W.T. Stanley unpubl.).

Conservation IUCN Category: Least Concern.

Geographic range is fragmented and the number of suitable habitats are declining.

Crocidura yankariensis YANKARI SHREW

Fr. Crocisure de Yankari; Ger. Yankari-Spitzmaus

Crocidura yankariensis Hutterer and Jenkins, 1980. Bull. Brit Mus. (Nat Hist.) Zool., 39: 305. Futuk (16 km E of Yankari G. R. boundary), Bauchi Province, N Nigeria.

Taxonomy Specimens of this species were previously misidentified as *C. somalica* (see Hutterer & Jenkins 1983). Synonyms: none. Chromosome number: 2n = 68, FN = 122 (Schlitter *et al.* 1999).

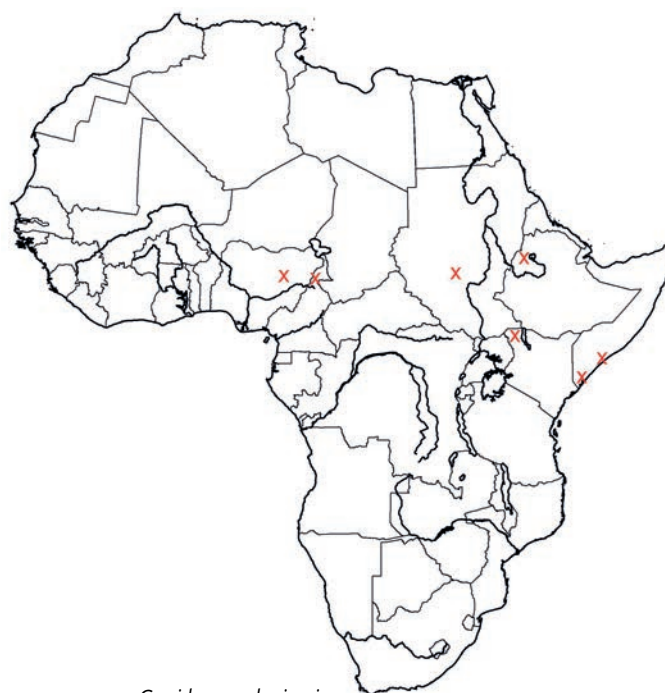

Description Very small species. Pelage short; hairs 2–3 mm. Dorsal pelage olive-brown; hairs grey at base, brown at tip. Ventral pelage smoky-grey or greyish-olive; hairs grey. Colours of dorsal and ventral pelage merge without delineation. Muzzle from nose-tip to eyes with fine short hairs, and without long vibrissae. Ears large, with short fine hairs; stiff bristles on inner folds. Fore- and hindfeet white. Lower part of hindlimb without brownish hair (cf. other *Crocidura* in which body hairs extend to ankle). Tail relatively long (ca. 67% of HB); bicoloured, brown above, whitish below; pilosity almost 100%. Skull: profile slopes gradually upwards anteriorly, then angles downwards sharply posteriorly; least interorbital width 3.9–4.1 mm (further details of skull in Hutterer & Jenkins 1983). Nipples: not known.

Geographic Variation A specimen from Ethiopia has dorsal pelage of deep fuscous, and ventral pelage of pale grey.

Distribution Endemic to Africa. Sudan Savanna BZ and parts of Somalia–Masai Bushland BZ. Recorded from Nigeria, Cameroon, Sudan, Ethiopia, NW Kenya and Somalia (Hutterer 2005b). Distribution very disjunct.

Habitat Primarily dry savanna. A specimen from Ethiopia was found amongst shrubs and boulders in wet grasslands (which are usually waterlogged during the wet season).

Abundance Uncertain. Present in owl pellets from near Yankari N. P., Nigeria (Hutterer & Jenkins 1980); also, but rarely (2 of 344 shrews), in pellets of Spotted Eagle-owls *Bubo africanus* from Awash N. P., Ethiopia (Demeter 1982).

Crocidura yankariensis

Remarks In Sudan and Ethiopia, coexists with *C. somalica* (a similarly small species; see profile for further details).

Conservation IUCN Category: Least Concern.

Crocidura zaphiri **ZAPHIR'S SHREW**

Fr. Crocidure de Zaphir; Ger. Zaphirs Spitzmaus

Crocidura zaphiri Dollman, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 509. Ann. Mag. Nat. Hist., ser. 8, 16: 66. Charada Forest, Kaffa, S Ethiopia.

Taxonomy Similar but smaller than *C. olivieri*. This species may also include *mutuae* and *suaelae* (see *C. viaria*), in which case it would be a widely distributed species (Hutterer & Yalden 1990, Hutterer 2005b). Synonyms: *simiolus*. Subspecies: none. Chromosome number: unknown.

Description Very large shrew. Dorsal pelage dull slaty-brown to cinnamon-brown. Ventral pelage slightly paler and greyer. Feet pale, contrasting with body colour. Tail of medium relative length (ca. 57% of HB), brown above and below; pilosity 95%. Second upper unicuspid smaller than third upper unicuspid; third upper molar moderately broad; talonid basin on third lower molar. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded in SW Ethiopia and SW Kenya (Dollman 1915a, Aggundey & Schlitter 1986).

Habitat No information.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.
Species insufficiently known.

Crocidura zimmeri **UPEMBA SHREW**

Fr. Crocidure d'Upemba; Ger. Upemba-Spitzmaus

Crocidura zimmeri Osgood, 1936. Field Mus. Nat. Hist. Publ., Zool. Ser. 20: 223. 'Lualaba River, Katobwe', near Bukama, Katanga Prov., DR Congo.

Taxonomy Species status of this little-known species is beyond doubt (Hutterer 2005b). Relationships unknown, but possibly part of the *C. turba* species complex. Synonyms: none. Chromosome number: not known.

Description Very large, strikingly coloured shrew. Dorsal pelage very dark blackish-brown. Ventral pelage considerably paler with a silvery tinge, not sharply separated from colour of dorsal pelage. Hindfeet dark brown. Tail of medium relative length (45% of HB),

*Crocidura zimmeri*

thickened at base, blackish and not bicoloured, with numerous long bristle hairs; pilosity 70–80%. Skull large and heavy, with dorsal profile somewhat arched or convex rather than straight; interorbital region broad; sagittal crest well developed and extending forward nearly to nasal bones. Dentition heavy but less so than in *C. oliveri*; second upper unicuspid slightly larger than third (Osgood 1936). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded only from the region of Upemba N. P., Katanga Province, S DR Congo.

Habitat Uncertain. Upemba N. P. is situated on the Kibara plateau and bordered in the west by the Lualaba (or Upper Congo) river and numerous lakes. The habitat of the plateau consists mainly of gently rolling grasslands at altitudes of between 1750 m and 1800 m. These are cut by numerous streams, which rise on the plateau and are lined with gallery forest. The grasslands are bordered by *Uapaca*-dominated woodland (Birdlife International 2006).

Abundance Rare. Known only by three specimens from type locality.

Remarks The species was found to co-exist with *C. oliveri* and *C. hirta* at Katobwe (Osgood 1936). There have been no known studies on this species since 1936 when the type series were collected.

Conservation IUCN Category: Data Deficient, previously Vulnerable.

GENUS *Myosorex*

Mouse Shrews

Myosorex Gray, 1838. Proc. Zool. Soc. Lond. 1837: 124 (publ. 1838). Type species: *Sorex varius* Smuts, 1832.

*Myosorex* sp.

The genus *Myosorex* contains 14 species occurring mainly in isolated mountain forests of central and south-east Africa. Populations on Bioko I. and the Cameroon Mts are widely isolated from populations in the mountains of the Rift Valley of eastern Africa and in the Eastern

Arc Mts of Tanzania. Most species are confined to montane forest or montane grasslands, and are less common in mid-elevation forests, lowland estuarine habitats and other vegetation close to water.

All species of *Myosorex* have dark-brown to blackish-brown pelage. Tail length varies from medium (42% of head and body length) to very long (84% in *Myosorex longicaudatus*) and does not have long white bristle hairs as in *Crocidura* and *Paracrocidura*. The limbs are of medium length as in other terrestrial shrews. Fore- and hindfeet are covered by small scales (cf. large in *Congosorex*) and the forefeet bear long claws (shorter in *Congosorex*, longer in *Surdisorex*). The outer ear is visible but embedded in the pelage. Eyes are small, but clearly visible (tiny in *Congosorex*, not visible in *Surdisorex*). The tip of the phallus of a male *Myosorex* is round (pointed in *Congosorex*). Cranially, *Myosorex* (and *Congosorex* and *Surdisorex*) differ from all other African shrews in having a pair of vascular foramina close to the suture

between the nasal and frontal bones (Figure 9). There are four upper unicuspid teeth in each jaw (see also Table 7).

Biological details are known for only a few species. They are active burrowers but also use existing runways in dense vegetation. They seem to be solitary and terrestrial. Some kind of social behaviour seems to exist because caravanning behaviour has been observed in some species (R. Baxter in litt.).

Myosorex and *Congosorex* are closely related and, on the basis of morphology, molecular genetics and similar adaptations for a semi-fossorial life-style, are placed together in the subfamily Myosoricinae (Hutterer *et al.* 2001, Quéroutil *et al.* 2001). *Surdisorex* is likely also to belong to this subfamily (see family profile). Partial reviews of *Myosorex* were provided by Heim de Balsac (1967, 1968a), Heim de Balsac & Lamotte (1956), Meester & Dippenaar (1978) and Stanley & Hutterer (2000). Although 14 species have been described, there are undoubtedly additional species, as yet undescribed.

The species currently recognized are not easy to distinguish, but usually differ in relative tail length and skull size (Stanley & Hutterer 2000). Since many species occur allopatrically, the locality is a major source for species determination. Sympatric species of the genus occur in southern Africa; they can be identified with keys provided by Meester *et al.* (1986) and Meester & Dippenaar (1978), except for *M. sclateri* and *M. tenuis*.

Figure 14. Skull and mandible of *Myosorex sclateri* (BMNH 4.12.3.14).

Rainer Hutterer

Myosorex babaulti BABAULT'S MOUSE SHREW (KIVU MOUSE SHREW)

Fr. Musaraigne des bois de Babault; Ger. Babaults Kivu-Spitzmaus.

Myosorex babaulti Heim de Balsac and Lamotte, 1956. *Mammalia* 20: 150. 'Kivu', DR Congo.

Taxonomy Formerly included in *C. blarina* but now recognized as a valid species (see Heim de Balsac & Lamotte 1956 and Dieterlen & Heim de Balsac 1979). A single specimen collected on Idjwi I. in L. Kivu (Allen & Loveridge 1942) is provisionally retained in *C. babaulti*. Synonyms: none. Chromosome number: not known.

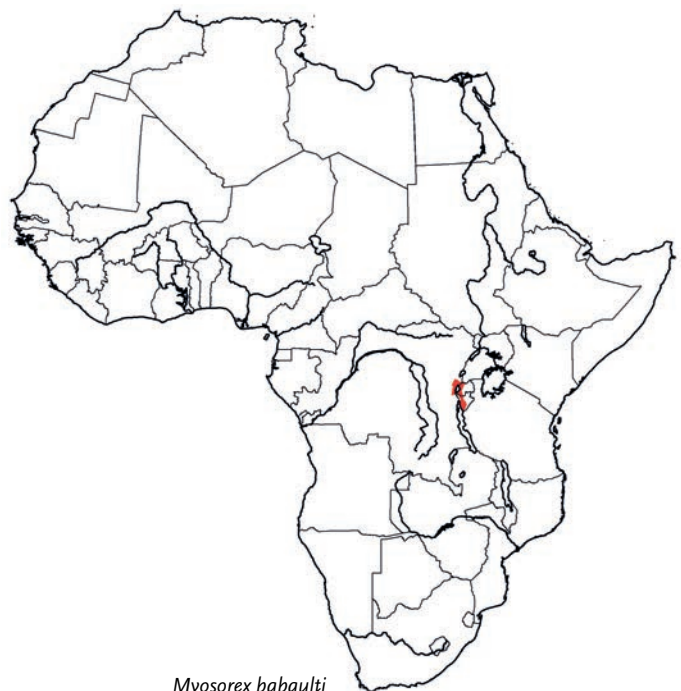

Description Medium-sized shrew, rather similar in form to a mole and to *M. blarina*. Pelage soft and dense, with slightly longer hairs at posterior end of body. Dorsal pelage uniformly blackish with a slight brownish tinge; hairs silvery ash-grey at base, brownish-black at tip. Ventral pelage paler than dorsal pelage; hairs ash-grey at base, brown at tip. Muzzle elongated. Eyes small with slit-like eye opening. External ears reduced and almost unpigmented; comprise only a forward directed broad flap (2–3 mm), which covers the wide opening of the auditory canal. Fore- and hindfeet brownish. Forefeet broad and mole-like with long claws (max. 2.5–3.0 mm). Tail of medium relative length (ca. 45% of HB), pale in colour, almost naked, with some short hairs below. Skull with well-marked interparietal bone and tiny much-reduced upper premolar (P^4). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex blarina. Similar in size and form except maxillary region and dentition less heavily built; M^3 smaller and more compressed

from front to back. Geographic distribution very close in E DR Congo (Rwenzori Mts only).

Myosorex babaulti

M. schalleri. Based on one juvenile specimen, head and body smaller (HB: 50–55 mm); tail longer (T: 44 mm) and relatively longer (ca. 80% of HB). Pelage entirely black. Apparently allopatric but distribution close (Itombwe Mts, E DR Congo).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Montane habitats in E DR Congo (west and east of L. Kivu, including Idjwi I. in L. Kivu), Rwanda and Burundi. Also recorded in Bwindi Impenetrable N. P., Uganda (Kasangaki *et al.* 2003), where it is apparently the only species of *Myosorex* (J. Kerbis in litt.).

Habitat Montane forests (including disturbed secondary montane forests) and, less frequently, swampy areas with *Cyperus latifolius* and shrubs (e.g. near Lwiro, west of L. Kivu [1750 m]). All localities are moist and shady (Dieterlen & Heim de Balsac 1979). Altitudinal range: ca. 1750–2300 m.

Abundance Uncertain, presumed to be rare.

Remarks Reduction of external ears and eyes, broad forefeet with long and strong claws, and a rather robust mole-like skull

suggest a subterranean life-style. One pregnant ♀ and one lactating ♀ recorded during the wet season (F. Dieterlen, unpubl.). Sex ratio (captures) 1 : 1 (n = 12).

Conservation IUCN Category: Near Threatened.

Myosorex blarina RWENZORI MOUSE SHREW (MOUNTAIN MOUSE SHREW)

Fr. Musaraigne des bois du Rwenzori; Ger. Rwenzori-Waldspitzmaus

Myosorex blarina Thomas, 1906. Ann. Mag. Nat. Hist. ser. 7, 18: 139. Mubuku Valley, Rwenzori Mts, Uganda. 10,000 ft (3048 m).

Taxonomy The forms *babaulti* and *zinki* were formerly subsumed within this species (see Heim de Balsac & Meester 1977), but are now considered valid species (see Dieterlen & Heim de Balsac 1979 for *babaulti*, and Stanley *et al.* 2005b and Hutterer 2005b for *zinki*). Synonyms: none. Chromosome number: not known.

Description Medium-sized dark shrew with a medium-length tail. Pelage thick and velvet-like. Dorsal pelage blackish-brown, slightly iridescent; hairs long (8 mm) interspersed with longer hairs (12–13 mm) on rump. Ventral pelage slightly more grey. Ears short, hidden by pelage. Fore- and hindfoot blackish; claws on forefoot very large. Tail of medium relative length (ca. 42% of HB), blackish, naked. Skull stout and heavy with prominent angle in squamosal region. Teeth small, anterior incisors delicate. First unicuspid the largest, second unicuspid just under half the size of the first, third unicuspid three-quarters the size of the first, fourth unicuspid minute. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex babaulti. Similar in size and form except maxillary region and dentition more heavily built; M³ larger and less compressed from front to back. Geographic distribution very close in E DR Congo but not recorded from Rwenzori Mts.

M. schalleri. Based on one juvenile specimen, head and body smaller (HB: 50–55 mm); tail longer (T: 44 mm) and relatively longer (ca. 80% of HB); skull shorter (CI: 8.9 mm). Pelage entirely black. Apparently allopatric but distribution close (Itombwe Mts, E DR Congo).

Distribution Endemic to Africa Afromontane–Afroalpine BZ. Restricted to the Rwenzori Mts of Uganda and DR Congo at 1920–4000 m. The published record of this species in Bwindi Impenetrable N. P. (Kasangaki *et al.* 2003) is incorrect (J. Kerbis in litt.)

Myosorex blarina

Habitat Occurs in several diverse habitats associated with changing elevation. Recorded from the lower forests along the Mubuku R. amidst bracken and at the edges of streams (1900 m), in the ericaceous zone at 3370 m (sphagnum moss in valley with *Lobelia*), and the alpine zone with *Lobelia* and *Senecio* (Kerbis Peterhans *et al.* 1998). The type series was taken near a stream in very swampy ground using ‘worms’ as bait (Thomas & Wroughton, 1910).

Abundance Rare. Comprised 11% of shrews ($n = 65$; 8 spp.) at six habitats in Rwenzori Mts (Kerbis Peterhans *et al.* 1998). Less common in forested habitats.

Remarks Terrestrial. Elongated foreclaws facilitate rummaging through leaf litter and humus. Mostly nocturnal, but was one of three specimens taken during the day (Kerbis Peterhans *et al.* 1998). Sexes collected in equal proportions ($n = 10$; FMNH). Two ♀♀ collected in Nov and May were not pregnant (FMNH).

Conservation IUCN Category: Endangered.

The rarity and restricted distribution are cause for concern.

Myosorex cafer DARK-FOOTED MOUSE SHREW

Fr. Musaraigne des bois à pieds sombre; Ger. Dunkelfuß-Waldspitzmaus

Myosorex cafer (Sundevall, 1846). Ofv. Kongl. Svenska Vet.-Akad. Forhandl. Stockholm 3 (4): 119. ‘E Caffraria interiore et Port-Natal’ (= Durban, KwaZulu–Natal Province, South Africa).

Taxonomy Originally described in the genus *Sorex*. The status of the Zimbabwe/Mozambique populations is uncertain (Meester 1958a); variation in chromosome number in the more central parts of the geographic range in South Africa suggests the presence of another species. The form *sclateri*, from KwaZulu–Natal, has for long been regarded as a subspecies of *M. cafer* (Meester *et al.* 1986), but is now recognized as a distinct species (Maddalena & Bronner 1992). Likewise *tenuis*, previously regarded as a subspecies (Meester *et al.* 1986), is now recognized as a valid species (Hutterer 2005b). Synonyms: *swinyi*. Subspecies: none. Chromosome number: $2n = 38$ or 40 (South Africa; Dippenaar *et al.* 1983).

Description Medium-sized shrew with medium-length tail. Dorsal pelage dark brown with buffy tinge; hairs slaty-grey at base, off-white to brown subterminal band, and dark-brown to black tip. Ventral pelage buffy-brown. Spring and autumn moults have a marked effect on pelage length, density and sometimes colour (Meester 1958b). Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet dark brown. Tail of medium relative length (ca. 50% of HB), dark-brown to black above, dark-brown below. Nipples: $0 + 3 = 6$.

Geographic Variation None recorded.

Similar Species

Myosorex longicaudatus. Tail on average longer (T: 66 [46–79] mm) and relatively longer (ca. 79% of HB). Allopatric but distribution fairly close along southern coast of South Africa.

M. sclateri. Pelage colour and hindfeet similar; skull on average larger (CI: 24.6 [23.9–25.5] mm). Sympatric in KwaZulu–Natal, South Africa.

M. tenuis. Head and body on average smaller (HB: 83.2 [75–92] mm). Skull on average shorter (CI: 21.5 [20.6–22.4] mm). Distribution close in Mpumalanga Province (formerly part of Transvaal), South Africa.

M. varius. Dorsal pelage mottled grey-brown to dark grey-brown; ventral pelage pale grey. Fore- and hindfeet pale grey. Tail pale to dark brown above, fawn to white laterally and below. Sympatric in part of South Africa; in the Amatola mountains of the Eastern Cape Province, *M. varius* is on average smaller than *M. cafer*.

Distribution Endemic to Africa. Zambezan Woodland, Highveld and Coastal Forest Mosaic BZs of southern Africa. Distribution disjunct. Recorded from three separate regions: (a) eastern highlands of Zimbabwe and adjacent Mozambique; (b) Soutpansberg Range in far northern South Africa and Swaziland; (c) eastern escarpment of Limpopo and Mpumalanga Province and into afro-montane and coastal forests of southern KwaZulu–Natal and the Eastern Cape Province (Meester 1958a, Smithers & Lobão Tello 1976, Smithers & Wilson 1979, Rautenbach 1982, Meester *et al.* 1986, Monadjem 1998a,c, Taylor, P. 1998).

Habitat In South Africa, typically occurs in forest although may also be found in montane grassland (e.g. in the Wolkberg, where *M. varius* is commonest in the adjacent forest [Rautenbach 1982]). More abundant in damp microhabitats. Appears to have stricter habitat requirements than *M. varius*, which occurs throughout its South African geographic range; *M. cafer* tending to be the commonest species in the forests and *M. varius* in the grasslands.

Abundance Reasonably common in suitable habitats. In the Amatola forests of Eastern Cape Province, South Africa, it and the

Woodland Dormouse *Graphiurus murinus* are the most common small mammals (trap success of 4%) (R. M. Baxter unpubl.).

Adaptations Predominantly nocturnal with a higher level of diurnal activity than *M. varius* (Baxter *et al.* 1979). In contrast to *M. varius*, no rooting and burrowing behaviour has been observed.

Foraging and Food Insectivorous. In Zimbabwe, prey includes spiders and earthworms, Lepidopteran larvae, Coleoptera, Isoptera, Isopoda and centipedes. Small amounts of seed and green plant material are also consumed (Churchfield 1985, Monadjem 1997).

Social and Reproductive Behaviour Mildly aggressive; vocalizations include a short squeak when encountering a strange conspecific. Scent-marking with lateral glands has been observed, and faecal piles are strongly scented. Saucer-shaped nests are built in captivity (Baxter & Meester 1980).

Reproduction and Population Structure Reproductive activity appears to occur during the wet season from Oct to Apr (Skinner & Smithers 1990, Taylor, P. 1998). Litter-size in Zimbabwe: 3 (2–4), *n* = 3 (Smithers & Wilson 1979); KwaZulu–Natal, South Africa: 3.5 (2–5), *n* = 6 (Taylor, P. 1998).

Predators, Parasites and Diseases Known predators include Barn Owls *Tyto alba* and African Grass-owls *Tyto capensis*.

Conservation IUCN Category: Least Concern.

Destruction of forest habitats is a potential threat to this species.

Myosorex eisentrauti EISENTRAUT'S MOUSE SHREW

Fr. Musaraigne des bois d'Eisentraut; Ger. Eisentrauts Waldspitzmaus

Myosorex eisentrauti Heim de Balsac, 1968. Bonn. Zool. Beitr. 19: 20. Pic Santa Isabel, Fernando Po (= Bioko I.), Equatorial Guinea. 2400 m.

Taxonomy The forms *okuensis* and *rumpii* (neither of which occurs on Bioko I.) were included in *C. eisentrauti* by Heim de Balsac & Meester (1977), but now both are regarded as distinct species (see Hutterer 1993, 2005a). Synonyms: none. Chromosome number: not known.

Description Small–medium, dark shrew. Pelage soft and dense with silky sheen; hairs ca. 6 mm. Dorsal pelage uniformly very dark blackish-brown; hairs dark grey at base, dark brown or dark chestnut-brown at tip. Ventral pelage slightly paler, dark brown with shot-silk appearance; hairs dark grey, very dark reddish-brown at tip. Ears small and inconspicuous, mostly concealed by pelage. Fore- and hindfeet brown, with dark scales, well covered by dark brown hairs; claws sharp and relatively long. Tail of medium relative length

(45–55% of HB), dark brown, not bicoloured, with many short dark brown hairs. Braincase high domed. First upper incisor moderately long and hooked. Third upper molar wide. Nipples: 2 + 0 = 4.

Geographic Variation None.

Similar Species

Myosorex rumpii. Apparently very similar but data limited. One specimen; Rumpi Hills, Cameroon.

Distribution Endemic to Bioko I. (Equatorial Guinea).

Habitat Found only on the Pic Santa Isabel at 2400 m and at 'Refugium' at 2000 m. At higher altitudes (Pic Isabel, ca. 3000 m),

lives in alpine grasslands. Habitat at lower altitudes (e.g. Refugium, 2000 m) is 'Schefflera montane forest' (1400–2600 m).

Abundance Uncertain; known only from a few specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Critically Endangered.

Myosorex geata GEATA MOUSE SHREW

Fr. Musaraignes des bois des montagnes Uluguru; Ger. Uluguru-Waldspitzmaus

Myosorex geata (Allen and Loveridge, 1927). Proc. Boston Soc. Nat. Hist. 38: 417. Nyingwa, Uluguru Mountains, Tanzania.

Taxonomy Originally described in the genus *Crocidura* but later placed in the genus *Myosorex* (Heim de Balsac 1967). Synonyms: none. Chromosome number: not known.

Description Small–medium, dark shrew. Pelage 6.5–7 mm (rump), 4.5–5.0 mm (neck and ventral pelage). Dorsal pelage rich dark brown; hairs slate-grey (75% of length), yellowish-gold subterminal band, dark brown at tip. Ventral pelage similar in colour to dorsal pelage, hairs lack brown tip. Fore- and hindfeet brown with scaly reticulation and small claws. Tubercles of hindfeet small. Tail of medium relative length (ca. 57% of HB), dark, only slightly bicoloured. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex kahaulei. HB on average larger (HB: 77 [70–84] mm), skull almost always slightly smaller (CI: 20.2 [19.7–20.8] mm); hindfoot tubercles larger and more rounded. Allopatric but distribution fairly close in Tanzania (Udzungwa Mts only; Stanley & Hutterer 2000).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only on Uluguru Mts, Tanzania.

Myosorex geata

Habitat Montane forests at 1345 and 1535 m. Allen & Loveridge (1927) recorded the holotype from 7500 ft (= 2250 m) and another specimen from 2000 ft (= 600 m).

Abundance Comprised 5% of shrews recorded at 1525 m (n = 103). Syntopic shrews in this sample include *C. monax* and *Sylvisorex howelli* (W.T. Stanley unpubl.).

Remarks In Jul and Aug (1996), none of the ♀♀ examined was pregnant (n = 2). On the basis of toothwear, all individuals (n = 6) were young adults (W.T. Stanley unpubl.). Sex ratio 1 : 1 (n = 6).

Conservation IUCN Category: Endangered.

The geographic range is limited and fragmented, and the number of suitable habitats is declining.

Myosorex kahaulei KHAULE'S MOUSE SHREW

Fr. Musaraigne des bois de Kihale; Ger. Kihaulis Waldspitzmaus

Myosorex kahaulei Stanley and Hutterer, 2000. Bonn. Zool. Beitr. 49: 19–29. Udzungwa Scarp Forest Reserve, Udzungwa Mts, Tanzania. 1460 m.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Small–medium, dark brownish shrew similar to *M. geata* in pelage characteristics. Dorsal pelage dark brown; hairs dark at base, brown at tip. Ventral pelage brown (but not as ‘rich’ as in *M. geata*). Hindfoot tubercles large and well rounded. Claws on feet robust. Tail of medium relative length (ca. 53% of HB). Skull robust (especially the rostrum), but slightly smaller than that of *M. geata*. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex geata. HB on average smaller (HB: 72.1 [68–75] mm), skull almost always slightly larger (CI: 20.9 [20.7–21.1] mm); hindfoot tubercles small. Allopatric but distribution fairly close in Tanzania (Uluguru Mts only; Stanley & Hutterer 2000).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only on Udzungwa Mts, Tanzania.

Habitat Wetter areas of montane forest including swampy areas and bamboo forests above 1400 m. Not recorded below 900 m in Udzungwa Scarp F. R. in 1995 (W. T. Stanley unpubl.).

Abundance Comprised 15% of shrews sampled (n = 108) at 1460 m and 2000 m on the Udzungwa Mts (1995; W. T. Stanley unpubl.).

Remarks Short tail and robust claws may allow for foraging in thick vegetation. While mostly nocturnal, diurnal movement has

been observed (W. T. Stanley, unpubl.). In Jul and Aug (1995), all specimens were adult, and one ♀ was pregnant. Embryo number: 2 (n = 1). Sex ratio 3 : 1 (n = 12) (W.T. Stanley unpubl.). Owl pellets found at 1800 m near Massiwe, Udzungwa Scarp Forest, contained one skull of *Myosorex kahaulei* (W. T. Stanley, unpubl.).

Conservation IUCN Category: Endangered.

The geographic range is limited and fragmented, and the number of suitable habitats is declining.

Udzungwa Mts, Tanzania (Stanley & Hutterer 2000, W. T. Stanley unpubl.)

Key Reference Stanley & Hutterer 2000.**William T. Stanley*****Myosorex longicaudatus* LONG-TAILED MOUSE SHREW**

Fr. Musaraigne des bois à longue queue; Ger. Langschwanz-Waldspitzmaus

Myosorex longicaudatus Meester and Dippenaar, 1978. Ann. Transvaal Mus. 31: 30. Diepwalle State Forest, 14 km NNE of Knysna (33° 57'S, 23° 10'E), Western Cape Province, South Africa.**Taxonomy** Polytypic. Dippenaar (1995) described *boosmani* as a subspecies on the basis of slight differences in cranial morphology and geographic location. Synonyms: none. Subspecies: two. Chromosome number: not known.**Description** Medium-sized shrew with long tail. Dorsal pelage dark grey heavily washed with greyish-yellow, brown or brownish-black; hairs slaty-grey at base, off-white to buffy subterminal band, dark-brown at tip. Ventral pelage somewhat paler, dark grey washed with brownish-black to dark brown, mostly paler than dorsal pelage; hairs slaty-grey, buffy at tip. Colours of dorsal and ventral pelage merge on flanks. Head slender with long, narrow pointed muzzle. Eyes small. Ears rounded. Fore- and hindfeet brownish-black, greyish yellow-brown, or dull yellowish-brown above. Tail relatively long (ca. 79% of HB); brownish-black above, usually somewhat to distinctly paler below. Males tend to weigh more than ♀♀. Nipples: 0 + 3 = 6.**Geographic Variation** Two subspecies can be distinguished only by discriminant function analysis.*M. l. boosmani*: Boosmansbos Forest and its ecotone in the Langeberg Mts; geographically isolated from the nominate subspecies by the dry Gouritz River valley. Differs from the nominate subspecies by its more slender rostrum, shallower braincase, usually narrower P³ and usually shorter but wider M³.*M. l. longicaudatus*: Knysna Forest from Lottering State Forest near Nature's Valley in the east to Ruitersbos State Forest north-north-west of Mossel Bay in the west.**Similar Species***Myosorex cafer*: Tail on average shorter (T: 44 [36–50] mm) and relatively shorter (49% of HB). Allopatric but distribution fairly close along southern coast of South Africa.*M. varius*: Tail almost always shorter (T: 42 [38–48] mm) and relatively shorter (ca. 50% of HB); fore- and hindfeet pale grey. Sympatric in extreme southern part of South Africa.**Distribution** Endemic to Africa. South-West Cape BZ. Occurs in the extreme southern parts of South Africa along almost the entire altitudinal gradient from 240 m above sea level near Nature's Valleyto 2000 m in the Outeniqua Mts north-north-west of Mossel Bay. Sympatric with *M. varius* throughout range.**Habitat** Primary forest, forest ecotones, fynbos and boggy grassland. Micro-habitats are always moist.**Abundance** It is usually readily trapped but is never as abundant as *M. varius*.**Remarks** When descending from objects, the terminal portion of the long tail is used in a prehensile fashion. The tail also braces the animal when it sniffs the air, forming a tripod with the hindlimbs. Insectivorous, but seeds have been found in stomach contents (Skinner & Smithers 1990). In captivity, readily eats a variety of insects, mealworms and minced meat, often dragging the food to the nest box before consuming it. In captivity, these shrews are surprisingly docile and can be handled with ease.*Myosorex longicaudatus*

Conservation IUCN Category: Vulnerable.

Destruction of forest and fynbos habitats is a potential threat to this species. Present evidence suggests that the subspecies *M. l. boosmani* in the Langeberg Mts should also be considered as 'Vulnerable'.

Myosorex okuensis OKU MOUSE SHREW

Fr. Musaraigne des bois du Mont Oku; Ger. Oku-Waldspitzmaus

Myosorex okuensis Heim de Balsac, 1968. Bonn. Zool. Beitr. 19: 20. L. Oku, Mt Oku, Bamenda Highlands, Cameroon. 2100 m.

Taxonomy Originally described as a subspecies of *Myosorex eisentrauti* (see Heim de Balsac 1968d, Heim de Balsac & Meester 1977), but cranially very distinct (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Small-medium very dark shrew. Pelage relatively long, soft and dense; hairs 7–8 mm. Dorsal pelage dark brownish-black; hairs dark blackish-grey, dark brown at tip. Ventral pelage similar in colour to dorsal pelage or slightly paler (depending on angle of view), with shot-silk appearance. Ears reduced, concealed by pelage and barely visible. Fore- and hindlimbs slightly pigmented, with dark brown short hairs; relatively long claws. Tail of medium relative length (ca. 55% of HB), dark brownish-black. Braincase high domed. First upper incisor moderately long and hooked. First upper unicuspid large, second and third smaller and subequal, fourth minute. Third upper molar medium. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex rumpii. Head and body probably larger (HB: 84 mm); tail probably shorter (T: 35 mm) and relatively shorter (ca. 40% of HB) but data limited (n = 1). Allopatric but distribution fairly close (Rumpi Hills, Cameroon).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only on the Bamenda Highlands, Cameroon (L. Manenguba, Mt Oku, Mt Lefo). Populations disjunct.

Habitat Montane forests.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Myosorex rumpii RUMPI MOUSE SHREW

Fr. Musaraigne des bois de Rumpi; Ger. Rumpi-Waldspitzmaus

Myosorex rumpii Heim de Balsac, 1968. Bonn. Zool. Beitr. 19: 20. Rumpi Hills, Cameroon. 1100 m.

Taxonomy Originally described as a subspecies of *M. eisentrauti*; however, Heim de Balsac was uncertain about the status of this taxon, and while he formally named it *M. eisentrauti rumpii*, he labelled all figures and the map with '*Myosorex rumpii*'. Now regarded as a full species (Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Medium-sized, dark short-tailed shrew. Pelage soft, dense and velvety with silky sheen; hairs ca. 6 mm. Dorsal pelage dark blackish-brown; hairs dark grey on basal two-thirds, blackish-brown or dark chestnut-brown on terminal third. Ventral pelage blackish-brown, paler than dorsal pelage (depending on angle of view) with shot-silk appearance; hairs dark grey on basal two-thirds, dark reddish-brown on terminal third. Head similar in colour to dorsal pelage. Fore- and hindfeet whitish with conspicuous brown scales, short blackish-brown hairs on upper surface; claws relatively long and sharp. Tail relatively short (ca. 40% of HB), blackish-brown, not bicoloured. First incisor moderately long and hooked. Third upper molar narrow. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex eisentrauti. Apparently very similar but data limited. Only known from Bioko I.

M. okuensis. Head and body probably smaller (HB: 72–73 mm); tail probably longer (40, 41 mm) and relatively longer (ca. 55% of HB), but data limited. Allopatric but distribution fairly close (Bamenda Highlands, Cameroon).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the type locality in the Rumpi Hills, Cameroon.

Habitat Not known.

Abundance Not known.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Listed as a species of conservation concern by Nicoll & Rathbun (1990).

Myosorex schalleri SCHALLER'S MOUSE SHREW

Fr. Musaraigne des bois de Schaller; Ger. Schallers Waldspitzmaus

Myosorex schalleri Heim de Balsac, 1966. C.R. Acad. Sci. Paris 263: 889. Nzombe (Mwenga), Itombwe Mts, E DR Congo.

Taxonomy Provisionally named by Heim de Balsac (1966) and fully described by Heim de Balsac (1967). The type locality was erroneously given as 'Albert N. P.' by Heim de Balsac & Meester (1977) but is located

in the Itombwe Mts (Hutterer 1986c). The description was based on a juvenile ♂, which still remains the only known specimen. The relation of the species within the genus is unresolved. Synonyms: none.

Description Very small (smallest species of the genus), comparable in size to *Sylvisorex granti*, with entirely black pelage and limbs (Heim de Balsac 1967). Pelage short and not dense. Tail relatively very long (ca. 80% of HB); appearing naked, without long bristles. Ear conch visible, not reduced or hidden in pelage. Skull small with an oval (not hexagonal) braincase and a narrow interparietal bone. Due to the juvenile condition of the holotype, the normal adult shape of the skull is not known. Dentition as in other *Myosorex*, but weaker. For a full description see Heim de Balsac (1967). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex babaulti. Head and body perhaps larger (HB: 79–91 mm); tail perhaps shorter (T: 34–40 mm) and relatively shorter (ca. 45% of HB). Pelage not entirely black, hairs ash-grey at base. Apparently allopatric but distribution close in E DR Congo.

M. blarina. Head and body larger (HB: 81–93 mm); tail probably shorter (T: 31–40 mm) and relatively shorter (ca. 42% of HB); skull longer (CI: 21.7–22.5 mm, $n = 3$). Apparently allopatric but distribution close (Rwenzori Mts of Uganda and E DR Congo).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the Itombwe Mts of E DR Congo.

Habitat Montane forest. The holotype was found dead on a forest road near Nzombe during a gorilla survey. Schaller (1963) provided a photograph of the site and commented: ‘A mountain rain forest covers the chaotic jumble of ridges and valleys in the Mwenga-Fizi region.’

Abundance Very rare. Known only from the type locality.

Remarks *Myosorex schalleri* seems to form, together with *Paracrociodura graueri*, part of the endemic small mammal fauna of the Itombwe Mts (Hutterer 1986c).

Conservation IUCN Category: Data Deficient, previously Critically Endangered.

Myosorex sclateri SCLATER'S MOUSE SHREW

Fr. Musaraigne de bois de Sclater (Musaraigne du Kwazulu); Ger. Sclaters Waldspitzmaus

Myosorex sclateri Thomas and Schwann, 1905. Abstr. Proc. Zool. Soc. Lond. 1905 (15): 10. Ngoye Hills, Zululand, South Africa.

Taxonomy Sometimes regarded as a subspecies of *M. cafer* (Meester *et al.* 1986). Differences in karyotype (Wolhuter in Smithers 1983) and habitat suggest that *sclateri* should be recognized as a valid species (see Hutterer 2005b), sympatric with *M. cafer*. *Myosorex sclateri* can also be distinguished from *M. cafer* and *M. varius* on biochemical evidence (Maddalena & Bronner 1992) and morphological grounds (T. Kearney in Taylor, P. 1998). Synonyms: *affinis*, *talpinus*. Subspecies: none. Chromosome number: $2n = 38$.

Description Large shrew but with considerable variation in size. Dorsal pelage bright reddish-brown or blackish-brown. Ventral pelage yellowish-brown. Feet broad and digits relatively long. Hindfeet brown to black. Tail short to medium (43–63% of HB), uniformly brown, maybe slightly paler below. Skull: CI = 24–27 mm (cf. Similar Species). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex cafer. Pelage colour and hindfeet similar; skull on average smaller (CI: 23.3 [22.1–24.3] mm). Sympatric in KwaZulu–Natal, South Africa.

M. varius. Dorsal pelage dull mottled grey-brown to dark grey-brown; hindfeet pale grey. On average smaller (HB: 83 [76–88] mm; T: 42 [38–48] mm). Skull shorter (CI: 20.3–22.4 mm). Sympatric in N KwaZulu–Natal, South Africa.

Distribution Endemic to Africa. Coastal Forest Mosaic BZ. Restricted to KwaZulu–Natal Province, South Africa.

Habitat Estuarine reed-beds and other wet habitats; also grassland and forest close to water. Coastal and lowland regions.

Abundance Fairly common (Taylor, P. 1998).

Remarks Habitat preferences rather similar to those of *M. varius* (Taylor, P. 1998).

Conservation IUCN Category: Near Threatened.

Although not uncommon in favoured habitats, distribution is very restricted.

Myosorex tenuis THIN MOUSE SHREW (TRANSSVAAL FOREST SHREW)

Fr. Musaraigne des bois du Transvaal; Ger. Transvaal-Waldspitzmaus

Myosorex tenuis Thomas and Schwann, 1905. Proc. Zool. Soc. Lond. 1905: 131–132. Zuurbron, Wakkerstroom Highlands, Transvaal, South Africa.

Taxonomy Traditionally considered as synonym (Meester *et al.* 1986) or subspecies (Smithers 1983) of *M. cafer*. Now recognized as valid species because of different karyotype (see Smithers 1983, Hutterer 2005b). Synonyms: none. Chromosome number: 2n = 40 (Wolluter in Smithers 1983).

Description Medium-sized dark shrew. Dorsal pelage dark brown. Ventral pelage paler, with a silvery wash in some specimens. Feet dark brown, slender with long claws. Ears smaller and less conspicuous than in *M. sclateri*. Tail of medium relative length (41–59% of HB), dark above, paler beneath. Skull moderately small (CI: 20–22 mm). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Myosorex cafer. Head and body on average larger (HB: 88 [78–105] mm). Skull on average longer (CI: 23.3 [22.1–24.3] mm).

Distribution close in Mpumalanga Province (formerly part of Transvaal), South Africa.

M. varius. Dorsal pelage mottled grey-brown to dark grey-brown. Very similar in size. Sympatric in Mpumalanga Province (formerly part of Transvaal), South Africa.

Distribution Endemic to Africa. Highveld BZ. Recorded from Mpumalanga Province (formerly part of Transvaal), South Africa; possibly also W Mozambique.

Habitat Thick grass at edge of stream (eight specimens), under a tree in forest (two specimens) and in a vlei (one specimen) (labels, BMNH). Recorded from 1600 m in Wakkerstroom Highlands, Transvaal (Thomas & Schwann 1905).

Abundance No information. Rarely collected.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Formerly considered as Vulnerable. Known only from a very restricted area.

Myosorex tenuis

Myosorex varius SOUTH AFRICAN MOUSE SHREW

Fr. Musaraigne des bois sud-africaine; Ger. Südafrika-Waldspitzmaus

Myosorex varius (Smuts, 1832). Enumer. Mamm. Cap. p. 108. Algoa Bay, South Africa (= Port Elizabeth, Eastern Cape Province, South Africa).

Taxonomy Originally described in the genus *Sorex*. Synonyms: *herpestes*, *pondoensis*, *transvaalensis*. Subspecies: none. Chromosome number: 2n = 40 or 42 (South Africa; Dippenaar *et al.* 1983).

Description Medium-sized shrew. Dorsal pelage mottled grey-brown to dark grey-brown; hairs slaty-grey at base, white to off-white subterminal band, dark-brown at tip. Ventral pelage pale grey, sometimes with yellowish tinge; hairs slaty-grey at base, white to fawn at tip. Colours of dorsal and ventral pelage merge gradually. Head slender with long, narrow pointed muzzle, eyes small, ears rounded. Fore- and hindfeet pale grey. Tail of medium relative length (ca. 50% of HB), pale to dark brown above, fawn to white laterally and below, with sparse hairs along its length. Nipples: 0 + 3 = 6.

Geographic Variation Individuals from higher altitudes in the Drakensberg Mts are significantly smaller (in HB, E and WT) than individuals from lower altitudes (Rowe-Rowe & Meester 1985a). In contrast, populations in Eastern Cape Province exhibit the opposite trend between sea level and 1800 m (R. M. Baxter unpubl.).

Similar Species

Myosorex cafer. Dorsal pelage dark brown with buffy tinge; ventral pelage buffy-brown. Fore- and hindfeet dark brown. Tail dark-brown to black above, dark-brown below. Sympatric in the Amatola mountains of the Eastern Cape Province, South Africa, where *M. cafer* is on average larger than *M. varius*.

M. longicaudatus. Tail almost always longer (T: 66 [46–79] mm) and relatively longer (ca. 79% of HB); fore- and hindfeet brownish-

black, greyish yellow-brown, or dull yellowish-brown above. Sympatric in extreme southern part of South Africa.

M. sclateri. Dorsal pelage bright reddish-brown or blackish-brown. Hindfeet brown to black. On average, larger (HB: 94 [81–114] mm; T: 51 [46–57] mm). Skull longer (CI: 23.9–25.5 mm). Sympatric in N KwaZulu–Natal, South Africa.

M. tenuis. Dorsal pelage dark brown. Very similar in size. Sympatric in Mpumalanga Province (formerly part of Transvaal), South Africa.

Distribution Endemic to Africa. Widespread in parts of South-West Arid (Karoo), South-West Cape, Highveld and Coastal Forest Mosaic BZs. Recorded from Lesotho, W Swaziland and the southern parts of South Africa. In South Africa, known from the eastern half of Limpopo Province, southwards and westwards through Mpumalanga, Gauteng, NE Free State and KwaZulu–Natal Provinces. Also occurs along the western coast of Northern Cape Province, southwards to Western Cape Province and eastwards across much of Eastern Cape Province (Rautenbach 1982, Lynch 1983, 1994, Meester *et al.* 1986, Monadjem 1998a, c, Taylor, P. 1998).

Habitat Savanna and grassland habitats, typically in dense, moist grassland. Also recorded in forest (Rautenbach 1982, Rowe-Rowe & Meester 1982a) and in drier regions along the west coast and in Karoo N. P. where mists provide a moist micro-habitat. Measurements in different micro-habitats along an altitudinal gradient indicate a relatively stable environment despite considerable variation in climate (R. M. Baxter & C. R. Brown unpubl.); it is probably this stability that allows this species (and possibly other species) to

occupy a diverse range of vegetation types. Recorded in grasslands, *Protea* woodlands, scrub, forest and *Erica*–*Helichrysum* habitats, from 1500–3000 m, in the Drakensberg Mts, South Africa (Rowe-Rowe & Meester 1982a).

Abundance Common in many habitats in the Drakensberg Mts, South Africa (Rowe-Rowe & Meester 1982a) and Eastern Cape Province (R. M. Baxter unpubl.). Recorded in all of ten montane habitats (1500–1800 m) in the Drakensberg Mts, where it was mostly the second most numerous small mammal after the rodent *Rhabdomys pumilio*, and at all of eight sub-alpine and alpine habitats where it was usually the most abundant small mammal (Rowe-Rowe & Meester 1982a). In Eastern Cape Province, abundance (as frequency of occurrence in traps) increased from 1.9% at 600 m to 3.0–7.7% at 1500 m and 6.3–11.5% at 1800 m (R. M. Baxter unpubl.).

Adaptations Terrestrial and generally nocturnal (Baxter *et al.* 1979) but becoming predominantly diurnal in mid-winter (Brown *et al.* 1997). This change in circadian rhythm is an adaptation that probably allows these shrews to conserve energy by resting in a well-insulated nest during the coldest hours of the night. Possess relatively long claws on the forefeet, and are active burrowers.

Foraging and Food Mostly insectivorous. Analysis of stomach contents indicates that feeding is largely opportunistic and changes seasonally (Rowe-Rowe 1986, Wirminghaus & Perrin 1992, Monadjem 1997). In the Drakensberg Mts, the commonest prey (frequency of occurrence, wet and dry seasons combined) are adult Coleoptera (58%), Hymenoptera (53%), Orthoptera (24%), Lepidoptera larva (22%), Coleoptera larva (20%), Arachnida (20%), Blattoidea (16%), Hemiptera (11%) and six other orders (each <10%) (n = 55; Rowe-Rowe 1986). In captivity, readily eats earthworms, locusts, grasshoppers, bagworms, termites and beetles (Goulden & Meester 1978). Small amounts of vegetable matter form part of the diet (Wirminghaus & Perrin 1992), and there is circumstantial evidence that green plant material might be important in initiating breeding in captivity (R. M. Baxter unpubl.). May be cannibalistic. Refection (rectum-licking) has been observed (Baxter & Meester 1980).

Social and Reproductive Behaviour Mostly an aggressive species, especially at the beginning of the breeding season. In captivity individuals need to be kept apart in order to avoid fighting and potential death. Both ♂♂ and ♀♀ maintain territories during the wet and dry season. Territory size is in the region of 0.08–0.2 ha and, in general, male and female territories have areas of overlap. Scent-marking of territories is performed using secretions from the lateral and chin glands and the faecal pile is strongly scented (Baxter & Meester 1980). When individuals are alarmed, they exude a strong odour that humans can smell several metres away (R. M. Baxter unpubl.).

Vocalizations include a short, sharp squeak when encountering strange conspecifics and when alarmed. This squeak is repeated frequently and interspersed with occasional drawn-out ‘chirrs’ during aggressive encounters. A soft ‘chittering’ is heard occasionally from male–female pairs, and when the young are nursed. The young emit a keening squeak during their first few days. Grooming includes scratching with the hindfeet, nibbling and licking of the fur and paws, and face-washing with the forepaws (Goulden & Meester 1978).

Myosorex varius

Courtship behaviour involves extensive chasing by the male (Goulden & Meester 1978). Nests of grass are spherical with 2–4 entrances, often at the end of a short burrow under a rock. Maternal care is well developed. The young nipple-cling from birth to Day 5 or 6, thereafter caravanning is observed until weaning. A female has never been observed to carry the young in her mouth (Baxter & Lloyd 1980).

Reproduction and Population Structure Geographic variation in the breeding season is apparent. Generally pregnancies occur in the wet season but can occur at any time if unseasonable rain falls (R. M. Baxter unpubl.). In most locations, breeding occurs from Aug, Sep or Oct to Feb–Apr (data from Gauteng Province, KwaZulu–Natal Province, Drakensberg Mts and Lesotho). However, year-round breeding occurs in the Western Cape, with most pregnancies in Jun–Sep (where there is winter rainfall) (R. M. Baxter unpubl.). Embryo number: 3.3 (1–6), mode 3, n = 125) but mean embryo number varies with location, e.g. Western Cape 2.5 (n = 26), KwaZulu–Natal midlands 3.0 (n = 26) (R. M. Baxter unpubl.), KwaZulu–Natal Drakensberg 2.8 (n = 19) (Rowe-Rowe & Meester 1982b) and Lesotho 3.8 (n = 45) (Lynch 1994). Larger litters occur in locations where the breeding season is shorter, e.g. Lesotho.

Young are born blind, naked and helpless. Development is rapid and weaning occurs at Day 20–24 when the young (HB: 75–78 mm) are almost adult size (HB: 84–87 mm) (Baxter & Lloyd 1980). Longevity is 12–16 months, with a die-off of old adults towards the end of the breeding season. In captivity, individuals survive for up to 2.5 years (R. M. Baxter unpubl.).

During the dry season, populations are usually composed of sub-adults (50–60%; toothwear class 2; Dippenaar 1977) and adults (ca. 30%; toothwear class 3) with a few older animals. Approximately two months after the start of the wet season, juveniles (toothwear class 1) first appear, and by mid and late wet season, the population is composed of juveniles (ca. 20%), subadults (40%) and adults (40%) (R. M. Baxter unpubl.).

Predators, Parasites and Diseases Remains of this species are often found in the pellets of Barn Owls *Tyto alba* (*inter alia* Baxter & Matshili 2003). Other known predators include Marsh Mongooses *Atilax paludinosus*, Striped Weasels *Poecilogale albinucha* and Zorillas *Ichonyx striatus*.

Conservation IUCN Category: Least Concern.

A widely distributed, common species.

Myosorex zinki KILIMANJARO MOUSE SHREW

Fr. Musaraigne des bois du Kilimanjaro; Ger. Kilimanjaro-Waldspitzmaus

Myosorex zinki Heim de Balsac and Lamotte, 1956. Mammalia 20: 148. South-east slope of Mt Kilimanjaro, Tanzania. 3700 m.

Taxonomy Described as a subspecies of *Myosorex blarina*, and often referred to as such (e.g. Heim de Balsac & Meester 1977, Shore & Garbett 1991). Synonyms: none. Chromosome number: not known.

Description Very large and distinctive dark shrew. Pelage soft, dense with silky sheen; hairs ca. 6 mm. Dorsal pelage uniformly dark greyish-brown with conspicuous shot-silk appearance; hairs dark grey at base, shiny brown at tip. Some hairs with subterminal band of white resulting in flecked appearance. Ventral pelage slightly to moderately paler (depending on angle of view) with shot-silk appearance; hairs grey, greyish-brown at tip. Ears inconspicuous and densely covered with hairs, well concealed by pelage. Fore- and hindfeet brown, darkly pigmented, well-covered with dark brown short hairs. Tail relatively short (ca. 38% of HB), blackish-brown, with dark brown short hairs above, brown below. Braincase high-domed. First upper incisor moderately long and hooked. Third upper molar wide. No sexual dimorphism in body and skull measurements. Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only at higher altitudes (2470–4000 m) on Mt Kilimanjaro, Tanzania (Grimshaw *et al.* 1997, Stanley *et al.* 2005b).

Habitat Montane forest, heathland, moorland, and the edges of alpine desert (Stanley *et al.* 2005b). One specimen collected on a grassy river bank (Shore & Garbett 1991).

Abundance Widely distributed along an elevational gradient ranging from 2470–4000 m (Stanley *et al.* 2005b); may be common in some localities.

Remarks This is the only species of *Myosorex* currently known to occur on Mt Kilimanjaro. No other information available.

Conservation IUCN Category: Vulnerable.

Myosorex zinki

GENUS *Paracrocidura*

Large-headed Shrews

Paracrocidura Heim de Balsac, 1956. Rev. Zool. Bot. Afr. 54: 137. Type species: *Paracrocidura schoutedeni* Heim de Balsac, 1956.

Paracrocidura schoutedeni.

The genus contains three species distributed in rainforest and montane forest habitats of central Africa, and has been recorded from Cameroon, Gabon, Equatorial Guinea, Congo, DR Congo, Central African Republic, Uganda, Rwanda and Burundi. The species in the genus are often found close to small streams, at altitudes of 600–2350 m.

The body form is that of a terrestrial shrew. The head is especially large (hence the vernacular name ‘large-headed shrew’) with long protruding incisors, and the ear pinnae are small, thinly haired and vertically inserted. The limbs are short (HF: 9–16 mm), and the tail is short (HB: 24–46 mm), thick and covered with long bristle-hairs (as in *Crociodura*). The pelage is short and uniformly dark brown. Females have only one pair of nipples. Skull characteristics include broad and flat braincase, narrow interorbital region, broad bimaxillary region, and three upper unicuspid teeth in each ramus (see also Table 7). The upper incisors are strongly hooked and have spade-like tips; upper and lower molars are very broad (Figure 15).

The biology of the species of this genus is not well known. One species lives in lowland forest, the two others in montane forest. Tree ferns and running water are typical characteristics of such habitats. It is assumed that Large-headed Shrews forage in leaf litter and under logs. The reduced number of nipples in ♀♀ and very low litter size (1–2) suggest a special but as yet not understood social organization and reproductive strategy.

Figure 15. Skull and mandible of *Paracrocidura schoutedeni* (ZFMK 22920, with some information from BMNH 63.1813).

The genus (and its three species) was revised by Hutterer (1986c). A study of 16s rRNA sequences placed *Paracrocidura* in one clade with *Crociodura* (Quérrouil *et al.* 2001). However, unique external and cranial features distinguish *Paracrocidura* from all other genera.

The three species of the genus are distinguished by absolute size, and especially by length of hindfoot and tail.

Paracrocidura graueri GRAUER'S LARGE-HEADED SHREW

Fr. Crociodure à grande tête de Grauer; Ger. Grauers Großkopfspitzmaus

Paracrocidura graueri Hutterer, 1986. Bonn. Zool. Beitr. 37: 81. Sibatwa, Itombwe Mts, DR Congo. 2000 m.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Medium-sized shrew. Pelage short and dense. Pelage uniform in colour; dorsal and ventral pelage dark brown (presumably – faded in the only specimen). Ears conspicuous but short, not concealed by pelage. Fore- and hindfeet pale and covered by very short hairs. Tail of medium relative length (ca. 55% of HB), unicoloured, paler than dorsal pelage; pilosity ca. 80%. Skull with a relatively long braincase and long rostrum. First incisor long and hooked. Third molar wide. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Paracrocidura maxima. Skull perhaps shorter (CI: 25.9 [25.1–26.9] mm); toothrow shorter (I^1-M^3 : 12.3–13.6 mm). Allopatric.
P. schoutedeni. Tail shorter (T: 34.5 [33–38] mm); hindfoot perhaps shorter (HF: 11.3 [10–13] mm). Allopatric.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the type locality in the Itombwe Mts, E DR Congo.

Habitat Montane forest.

Abundance Very rare; known only from the holotype.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Paracrocridura maxima Heim de Balsac, 1959. Rev. Zool. Bot. Afr. 59: 26. Tshibati, E DR Congo.

Taxonomy Originally described as a subspecies of *Paracrocridura schoutedeni*, but regarded as a full species by Hutterer (1986c, 2005a). Genetic data suggest that the genus *Paracrocridura* is a monophyletic clade, recently derived from the genus *Crocridura* (Quéroutil *et al.* 2001). Synonyms: none. Chromosome number: not known.

al. 2003) and Mgahinga–Gorilla N. P. (Uganda), Nyungwe N. P. (Rwanda) and Kibira N. P. (NW Burundi); and on the western side from Kahuzi-Biega N. P. (E DR Congo). Altitude range: mostly 1600–2680 m, with one record from Irangi, E DR Congo (850 m).

Description Large blackish shrew with dense, very short pelage; hairs 3–4 mm. Dorsal pelage and ventral pelage blackish-grey or dark grey-brown. Head large, with small ears. Tail of medium relative length (ca. 53% of HB), very fat, with long (4–5 mm) bristle hairs; pilosity 90%. Skull: braincase box-shaped in dorsal view (figured in Thorn and Kerbis Peterhans 2009); incisors spade-like at tip. Temporalis muscles well developed. Nipples: 0 + 1 = 2, inguinal and bifurcate.

Geographic Variation None recorded.

Similar Species

Paracrocridura graueri. Skull perhaps longer (CI: 27.7 mm); tooththrow perhaps longer (I¹–M³: 14.2 mm, n = 1). Allopatric.

P. schoutedeni. Hindfoot shorter (HF: 11.3 [10–13] mm); tail almost always shorter (T: 34.5 [33–38] mm); skull shorter (CI: 22.1–23.2 mm). Allopatric.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ. Recorded only in eastern Africa on both sides of the Albertine Rift Valley. Recorded on the eastern side from Rwenzori Mts (DR Congo and Uganda). Bwindi-Impenetrable N. P. (Kasangaki *et*

Paracrocridura maxima

Habitat Mostly recorded from montane forest (with one record from Irangi in lowland rainforest). Specimens have been captured in understorey habitats in primary and secondary forest, *Brillantasia* swamp forest, and beside a stream running through *Cyperus* swamp. Not recorded in alpine habitats (e.g. above treeline).

Abundance Probably rare – only about 19 specimens known at the present time. May be locally common as suggested by three specimens captured at Lwiro Falls (E DR Congo) during three days. Represented 3.4% of the soricid fauna ($n = 117$; 14–15 spp., captured in conventional traps and pitfall traps) in Bwindi-Impenetrable N. P. (Thorn & Kerbis Peterhans 2009) and 0.5% ($n = 207$; 17–18 spp.) in Kibira N. P., Burundi at 1600–2459 m.

Remarks A captive ♀ (WT: 20.6 g) gave birth to a full-term foetus (1.6 g, crown–rump length = 25 mm) on 4 April 1996 (Ruhija, Uganda). This ♀ was remarkable in the possession of a single pair of enlarged and bifurcate teats.

Conservation IUCN Category: Near Threatened.

This species is threatened because of its rarity and very restricted geographic range; in this respect it is similar to the other endemic species of the Albertine Rift Valley.

Fr. Crocidure à grande tête de Schouteden; Ger. Schoutedens Großkopfspitzmaus

Paracrocidura schoutedeni Heim de Balsac, 1956. Rev. Zool. Bot. Afr. 54: 137. Tshimbulu, Lubondaie, Kasai, DR Congo.

Taxonomy The subspecies *camerunensis* from Mt Cameroon (Heim de Balsac 1968b) is not currently recognized (Hutterer 2005b). Synonyms: *camerunensis*. Subspecies: none. Chromosome number: not known

Description Small–medium shrew with short dense pelage. Dorsal and ventral pelage blackish-brown. Short, robust snout. Ears small and covered with short, fine grey hairs. Hindfeet short with naked soles. Tail of medium relative length (ca. 50% of HB), thick; pilosity ca. 100%. Incisors with laterally flattened cutting edge. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Paracrocidura graueri. Tail longer (T: 46 mm, $n = 1$); hindfoot perhaps longer (HF: 14.8 mm, $n = 1$). Allopatric.

P. maxima. Hindfoot longer (HF: 15.1 [14–16] mm); tail almost always longer (T: 42.8 [37–48] mm); skull longer (CI: 25.1–26.9 mm). Allopatric.

Crocidura caliginea: Tail with only a few long hairs (pilosity 20–30%); rostrum shorter.

Distribution Endemic to Africa. Rainforest BZ (mainly West Central and South Central Regions). Recorded from Cameroon, Congo, Gabon, Central African Republic and S DR Congo (Hutterer 1986c).

Habitat Found in a variety of forest and forest edge habitats at mid-altitudes up to ca. 950 m (Hutterer 1986c). Considered as a typical member of the fauna of the lowland rainforest of the Congo Basin

(Goodman & Hutterer 2004). On Mt Doudou, Gabon, occurred at 110 m and 375 m, but not at 625 m (Goodman & Hutterer 2004).

Abundance May be quite common and, where present, represents 8–24% of shrews in various communities as follows: 11% at Belinga-Makokou (third most numerous after *Crocidura poensis* [48%] and *Sylvisorex johnstoni* [25%]; $n = 160$; 11 spp.; Brosset

Paracrocidura schoutedeni

1988); 24% at Moueva, SW Gabon (second commonest species after *S. johnstoni* [40%]; $n = 144$; 9 spp.; Nicolas *et al.* 2003); 13% at Minkébé Forest, Gabon (= third commonest species [with one other]; $n = 30$; 11 spp.; Goodman *et al.* 2001); 8% at Korup N. P. Cameroon (= third commonest species; $n = 24$; 9 spp.; Hutterer & Schlitter 1996); 11% at Mt Doudou, Cameroon (= fourth commonest species; $n = 56$ shrews captured at 110 m and 375 m; 9 spp.; Goodman & Hutterer 2004); 10% at Mt Alen, Gabon (third commonest species; $n = 40$; 8 spp., Lasso *et al.* 1996); and 11% at Ngotto, Central African Republic (fourth commonest species; $n = 81$; 11 spp.; Morvan *et al.* 1999).

Remarks Embryo number: 1.7 (1–2), $n = 4$ (Beling-Makokou, Gabon; Brosset 1988). Capture rates were changeable throughout the year in Ngotto, Central African Republic, with peak abundance recorded during May and Nov (Barrière & Nicolas 2000). It was the second most abundant species of shrew in small carnivore scats (frequency of occurrence: 24.1% of 311 scats) collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995, Ray 1998).

Conservation IUCN Category: Least Concern.

GENUS *Ruwenzorisorex*

Rwenzori Shrew

Ruwenzorisorex Hutterer, 1986. Z. Säugetierk. 51: 260. Type species: *Sylvisorex suncoides* Osgood, 1936.

Ruwenzorisorex suncoides.

Ruwenzorisorex is a monotypic genus distributed in the Albertine Rift Valley (E DR Congo, W Uganda, Rwanda and Burundi). The single species lives in shallow streams and swamps in montane forest.

Ruwenzorisorex is the only genus of African shrews with characteristics for a semi-aquatic life-style, such as water-repellent pelage, reduced ears, a slightly bicoloured tail and an enlarged brain with an expanded foramen magnum (Stephan *et al.* 1991). In some respects it resembles *Sylvisorex*, with which it was previously associated (Osgood 1936) – both species have a similar external appearance (naked tail) and possess an extra unicuspid tooth. However, *Ruwenzorisorex* is larger than any species of *Sylvisorex*, the upper and lower teeth are heavy and unique in shape (Hutterer 1986d), the lower first incisor is without denticulations and the skull is dorsoventrally compressed and concave when viewed laterally (Figure 16). Dental similarity with *Suncus* (small and medially inset fourth upper unicuspid, P⁴) was first pointed out by Osgood (1936), despite his allocation of the species to *Sylvisorex*. The close relationship between *Suncus* and *Ruwenzorisorex* has since been supported with

Figure 16. Skull and mandible of *Ruwenzorisorex suncoides* (ZFMK 148267).

genetic data (Quéroutil *et al.* 2001). Additional information and a key to the genus are given in Thorn & Kerbis Peterhans (2009) (see also Tables 7 and 8).

Rainer Hutterer & Julian C. Kerbis Peterhans

Ruwenzorisorex suncoides RWENZORI SHREW

Fr. Musaraigne du Rwenzori; Ger. Rwenzori-Spitzmaus

Ruwenzorisorex suncoides (Osgood, 1936). Field Mus. Nat. Hist. Publ., Zool. ser. 20: 217. Kalongi, western slope of Rwenzori Mts, E DR Congo. 7000 ft (2135 m).

Taxonomy Originally described as a species of *Sylvisorex* (Osgood 1936). Transferred to the new genus *Ruwenzorisorex* by Hutterer (1986d). More recently aligned with *Suncus* (Quérrouil *et al.* 2001) on the basis of molecular characteristics. Synonyms: none. Chromosome number: not known.

Description Large dark shrew with small ears and woolly, water-repellent pelage. Dorsal pelage blackish-grey, ticked with paler grey; hairs slate-grey at base, brownish at tip; 6 mm long. Long, pale-coloured guard hairs on rump. Ventral pelage slate-grey; hairs grey at base, pale grey or brownish at tip. Muzzle swollen, with well-developed facial vibrissae. Eyes small. Ears small, not protruding from pelage. Fore- and hindfeet without any special adaptations for aquatic life; claws 1–1.3 mm in length. Tail relatively short (ca. 40% of HB), slightly bicoloured, dark above, paler below especially at terminal end, and without long bristle hairs. Skull elongated, dorsoventrally compressed, concave profile in lateral view, with four unicuspid (I^2 , I^3 , C, P^3); lower incisor smooth, without denticulations (see also Table 8 and genus profile; Thorn and Kerbis Peterhans [2009]). Nipples: not known.

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ on both sides of the Albertine Rift Valley extending marginally into the Rainforest BZ of E DR Congo. Recorded from Irangi, Kalongi and Rwenzori Mts (E DR Congo), Uwinka (Nyungwe N. P., Rwanda), Bwindi-Impenetrable N. P. (Uganda) and Bururi Forest and Kibira N. P. (Burundi). Not recorded from the Ugandan side of the Rwenzori Mts.

Habitat Found near clear, shallow streams in montane forest (usually 1800–2350 m) but one record at 850 m (Irangi, E DR Congo). Also typically found by clear streams overhung with herbaceous undergrowth. The forested stream habitats where it has been collected in Burundi are characterized by scattered *Syzygium*, *Symphonia*, *Arundinaria* (bamboo) with *Cyathea* (tree ferns) and *Tabernaemontana*. The first record in Uganda was from a stream meandering through *Brillantasia* swamp (Bwindi-Impenetrable N. P., Uganda; Kasangaki *et al.* 2003). Not recorded from alpine habitats.

Abundance Extremely rare, known by only about ten specimens. This status is probably accurate because the large size of this species allows it to be caught by traditional collecting methods.

Remarks Semi-aquatic. Found exclusively along clear shallow streams (less than 20 cm deep) in montane forests. Exclusively nocturnal. Attracted to animal baits (e.g. fish and worms). The short dense water-repellent pelage, bicoloured tail and small ears are typical of semi-aquatic small mammals, but other characteristics often associated with such mammals (e.g. feet fringed with stiff hairs, webbed feet, keel on the tail) are not present. The enlarged medulla oblongata and enlarged foramen magnum are associated with an

Ruwenzorisorex suncoides

expanded trigeminal nerve system, which provides enhanced tactile acuity to the facial vibrissae when foraging in shallow streams; such an adaptation is also typical of other semi-aquatic mammals (Stephan *et al.* 1991).

Conservation IUCN Category: Vulnerable.

Considered to be threatened because of its rarity, very restricted geographic range, and specific micro-habitat requirements. The conservation threats to this species are similar to those of other endemic species of the Albertine Rift Valley. Of particular concern for this species are the detrimental effects of coltan mining on the streams in E DR Congo and NW Burundi.

Measurements

GENUS *Scutisorex*

Armoured Shrew (Hero Shrew)

Scutisorex Thomas, 1913. Ann. Mag. Nat. Hist., ser. 8, 11: 321. Type species: *Sylvisorex somereni* Thomas, 1910.

Figure 17. Skull and mandible of *Scutisorex somereni* (ZFMK 68.514).

A monotypic genus, belonging to the subfamily Crocidurinae (although, because of its very special characteristics, Heim de Balsac & Bourlière [1955] placed it in its own subfamily, Scutisorinae). The genus occurs only in rainforests and montane forests of NE DR Congo, Uganda, Rwanda and Burundi.

The genus is characterized primarily by the unique structure of the vertebral column (see species profile). Other characteristics include large size, and large skull sculptured with irregular bony ripples on the dorsal surface of the braincase (Figure 17). The teeth show similarities to those of *Sylvisorex*: comparatively small size, and lower horizontally placed incisors with denticulations. Dental formula: $I^{3/1}, C^{1/1}, P^{2/1}, M^{3/3} = 30$. There are four

upper unicuspid teeth behind I^1 (I^2, I^3, C, P^2); P^3 is well developed and molar-like with cusps. Further characteristics are given in the species profile.

Although *Scutisorex* has evolved to a giant shrew, it shows fewer modifications than the giant species of *Crocidura* and *Suncus* (Heim de Balsac & Lamotte 1957). Its origin can be found in the archaic evolutionary line of *Sylvisorex*, but the early point of divergence is a matter of speculation. Genetical studies place *Scutisorex* next to *Sylvisorex* (Quérouil *et al.* 2001).

There is a single species, *Scutisorex somereni*.

Fritz Dieterlen

Scutisorex somereni ARMoured SHREW (HERO SHREW)

Fr. Musaraigne cuirassée; Ger. Schildspitzmaus (Panzerspitzmaus)

Scutisorex somereni (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 6: 113. Kyetume, near Kampala, Uganda.

Taxonomy Originally described in the genus *Sylvisorex*. *Scutisorex somereni* is endemic to the Albertine Rift Valley (and nearby regions) and considered as the only species in the genus. The form *congicus* (Thomas 1915) from NE DR Congo was described as ‘probably only superficially distinct from the nominate race’ (Heim de Balsac & Lamotte 1957, Heim de Balsac & Meester 1977) and is now considered as a synonym. Synonyms: *congicus*. Subspecies: none. Chromosome number: not known.

Description Very large shrew with a unique and extraordinary vertebral column. Dorsal pelage long (15–17 mm on rump), dense, soft and woolly with projecting guard hairs. Dorsal pelage blackish-grey with a brownish (but variable) tinge, hairs sometimes with white tip. Ventral pelage similar to dorsal pelage, rather uniform in colour. In most adult specimens, dorsal and ventral pelages may have yellowish and brownish stains, mostly irregular in shape, due to secretions from the lateral glands. Muzzle, ears, upper surface of fore- and hindfeet blackish-brown. Tail relatively long (ca. 63% of HB), darkly pigmented and with short fine blackish hairs; pilosity 0%. Skull large and robust, with enormously developed lambdoid crests projecting posteriorly

beyond the level of the condyles (forming a ‘shield’ over the back of the skull). In old individuals, low sagittal crest present on the cranium. On both sides of the crest, the surface is not smooth, but sculptured with irregular bony ripples (as in *C. goliath* to a lesser extent). Nipples: $0 + 2 = 4$. The special characteristics of the vertebral column (see below) are not visible exteriorly.

Geographic Variation None recorded.

Distribution Endemic to Africa. Rainforest BZ (East Central Region), Afromontane–Afroalpine BZ (Albertine Rift Valley) and parts of Eastern Rainforest–Savanna Mosaic. Distribution disjunct. Recorded from NE and E DR Congo (Kisangani, Bafwasende, Medje, Ituri, Irangi, Semliki R., Rutshuru, mountains west of L. Kivu); Rwanda (Rugege Forest, now Nyungwe Forest); NW Burundi (Kibira N.P.); and Uganda (east of L. Albert, near Semliki R., east of L. Edward, west of the Victoria Nile including near Kampala) (Allen 1917b, Pirlot 1964, Rahm & Christiaensen 1963, Rahm 1966, Elbl *et al.* 1966, Kingdon 1974, Dieterlen & Heim de Balsac 1979, Hutterer *et al.* 1987, Cullinane & Aleper 1998, Dudu *et al.* 2005).

Habitat Lowland and montane forests from ca. 400 m (near Kisangani, DR Congo) to ca. 2500 m (highlands of E DR Congo and Rwanda). Also recorded, less frequently, from secondary lowland forests and montane bamboo (Dieterlen & Heim de Balsac 1979). Allen (1917b) reported similar habitats in NE DR Congo. Not recorded from open habitats, or from swamps and marshes. Kingdon (1974) recorded the habitat in Uganda as mainly swampy, but the species is not found in such habitats in DR Congo.

Abundance Uncommon. Comprised 4.8% (seven individuals) of small mammals trapped in montane forest at Rugege Forest, Rwanda (in Aug and Sep) (Dieterlen & Heim de Balsac 1979). In Masako Forest, DR Congo, comprised 7% of shrews (5 of 72; 9 spp.) and was the equal fourth commonest species (Dudu *et al.* 2005).

Adaptations The structure of the vertebral column is unique. Like most other mammals *Scutisorex* has seven cervical, 14 thoracic and five sacral vertebrae; but 11 (rather than the usual five) lumbar vertebrae. The vertebral column is heavily and strongly built. Although the cervical vertebrae are similar in structure to those of other mammals, the vertebrae from about the mid-thoracic region to last lumbar vertebra (and especially in the mid-lumbar region) are highly modified. The unique features of each of these vertebrae

Figure 18. *Scutisorex somereni*. (a) Skeleton. (b) Myology. (c) Details of lumbar region of vertebral column to show the interlocking pattern of tubercles (after Cullinane & Aleper 1998).

are increase in size and diameter, and profuse development of spines (called trabeculae or tubercles) arising mainly on the lateral sides of each vertebra. The spines face forwards and backwards and interlock with each other and with adjacent vertebrae (Figure 18). The arrangement provides great strength. The relative mass of the spine (3.97% of body mass) is considerably larger than in other mammals (0.69–1.58% in 12 other species of small mammals) (Cullinane *et al.* 1998). The increase in size and mass, and the unique structure, allows the spine to resist large compressive forces and to resist axial torsion. The ribs have larger diameters than expected for an animal of this size, and show similarities in structure to those of fossorial small mammals. Paradoxically, the appendicular skeleton (limbs) does not show any modifications for handling heavy loads or compression. The unique structure of the vertebrae has resulted in modifications of some of the spinal muscle groups (Cullinane & Aleper 1998). Locomotion in this species is ‘serpentine’ and unlike that of other shrews; undoubtedly the highly modified vertebral column reduces mobility to some extent (particularly in the sagittal plane). When standing, the vertebral column is slightly arched, especially behind the shoulder blade where the thickened part of the vertebral column begins, and consequently the rib cage is more vertical than horizontal. The strength and protective ability of the vertebral column is well illustrated by Herbert Lang (in Allen 1917b) who described how a local man (of about 160 pounds) balanced himself on one leg on the back of an Armoured Shrew for several minutes; when released, the shrew shook itself and seemed none the worse for the experience. Although Kingdon (1974) suggested that the structure of the vertebral column may be due to the fact that Armoured Shrews live in swamps and need to get the body well clear of the ground (as do other small mammals without any special modifications to the vertebral column), Ahmed & Klima (1978), Seip (1980), Schäfer (1980) and Cullinane *et al.* (1998) concluded that there is no known satisfactory ecological, behavioural or functional explanation for this unique vertebral morphology.

Studies on the embryos of Armoured Shrews show that the special characteristics of the vertebral column are visible in embryos. The enlarged vertebrae and tubercles are formed as cartilage and then ossified (as occurs during the development of any other mammal); they are not formed as secondary ossifications later in life (Ahmed & Klima 1978), nor because of a modified calcium–phosphorus metabolism as suggested by Heim de Balsac & Lamotte (1957).

The intestine is longer than in any other species of shrew (396.0 ± 43.5 mm, $n = 5$), a condition partly related to the large size of the shrew. Of greater interest is the high intestine/body length ratio of 3.7, which is considerably greater than for the other seven other species of smaller shrews (typically 2.1–2.9) in Masako Forest, DR Congo (Dudu *et al.* 2005). The significance of the relatively long intestine is uncertain.

Foraging and Food During foraging ‘the deeply grooved nose is moved in every direction and continually quivering ... the undersides of leaves and even stones are inspected. Fair sized pebbles, pieces of bark and decayed wood [are] turned over and pulled away with the assistance of the incisors’ (Herbert Lang in Allen 1917b). Dewdrops may be licked from the margins of the leaves or grasses (Allen

1917b). Diet, as indicated by analysis of stomach contents ($n = 5$), includes earthworms (100% frequency of occurrence); Diptera larvae, Diplopoda, Araneae (all 60%); adult Coleoptera, Formicidae, Acari (all 40%); and Heteroptera, Isoptera, Blattodea, Acrididae, Chiloptera (all 20%) (Dudu *et al.* 2005; Masako Forest, DR Congo). Of nine species of shrews in Masako Forest, DR Congo, only *S. somereni* ate earthworms. Prey size included a greater proportion of prey >30 mm in length than for any other species of shrew (Dudu *et al.* 2005).

Social and Reproductive Behaviour Scent marking behaviour appears to have high intra-specific (and possibly inter-generic) importance. On each side of the rump, adult individuals have a gland producing a strong-smelling yellow secretion (see Description). The odour is very characteristic and can be detected by humans at a distance of 5 m, e.g. when trapped or when running on the forest floor (Dieterlen & Heim de Balsac 1979). Captive specimens show very conspicuous marking postures and rhythmic rubbing with the hindquarters, suggestive of territorial marking (Kingdon 1974). The behavioural characteristics of Armoured Shrews are unknown. However, they have ‘a mild disposition’, which could suggest that they are more social than other species of shrews (Kingdon 1974) but this needs confirmation.

Reproduction and Population Structure Reproduction in rainforest habitats of E DR Congo has been recorded from Dec to Aug (no data from Sep to Nov). Pregnancy rate was higher during wet season (Dec–Apr; nine ♀♀ pregnant/lactating, three non-pregnant) than during the dry season (Jun–Aug; seven ♀♀ pregnant/lactating, nine non-pregnant). Embryo number: 1.85 (1–3), $n = 14$ ♀♀; mode 2 (Dieterlen & Heim de Balsac 1979). In Uganda, in May, two ♀♀ were lactating and three ♀♀ were not lactating (Kingdon 1974).

Predators, Parasites and Diseases Ticks (*Ixodes alluaudi* and *Ixodes* sp.) have been recorded from this species in Rugege Forest, Rwanda (Elbl *et al.* 1966).

Conservation IUCN Category: Least Concern.

GENUS *Suncus*

Dwarf Shrews

Suncus Ehrenberg, 1832. In: Hemprich and Ehrenberg. Symb. Phys. Mamm. 2: k. Type species: *Suncus sacer* Ehrenberg, 1832 (= *Sorex murinus* Linnaeus, 1766).

Suncus lixus.

The genus *Suncus* contains 18 species worldwide, of which nine species occur in Africa (Hutterer 2005b) – one of which has probably been introduced. The genus has a large geographic range, which also includes the Middle East, Madagascar, India, Sri Lanka, South-East Asia and China. In Africa, the distribution of each species is limited in extent and patchy, and the genus is not represented in western Africa nor in arid habitats.

The genus (in Africa) is characterized by very small size (all species weigh less than 8 g and the two smallest weigh only 1.5–2.5 g), short or long tail (ca. 40–65% of HB) with long hairs (as in *Crociodura* and *Paracrociodura*), large naked ears and small eyes. The skull is small with flattened braincase and four upper unicuspid (although the fourth unicuspid is often very small and may be vestigial). Dental formula: $I^{3/2}, C^{1/0}, P^{2/1}, M^{3/3} = 30$ (Figure 19). There are two exceptions to the above: (1) *Suncus murinus*, an Asiatic member of the genus, which is presumed to have been introduced in historical times into coastal East Africa, is very large (weight 67–105 g); (2) *Suncus megalura* has a relatively extremely long tail (ca. 118% of HB), long hindfeet and is scansorial; this species has previously been allocated to *Sylvisorex* (e.g. Hutterer 1993), but genetic data show that it should be allocated to *Suncus* (Quérrouil *et al.* 2001). See also Table 7.

These shrews are capable of living in a wide range of habitats, although moister habitats are preferred. The small size of most species suggests that thermoregulation is likely to be a major determinant of ecology and metabolism. Several species are associated with termitaria, where a moist, warm and constant environment (and plenty of food) provide a suitable environment for such a small

Figure 19. Skull and mandible of *Suncus murinus* (ZFMK 84.550).

mammal. Physiological studies on the small species of the genus would be of great interest.

Phylogenetically, *Suncus* is placed between *Crociodura* and *Sylvisorex* (Heim de Balsac & Lamotte 1957). The three genera are closely related and similar. Some authors (e.g. Harrison & Bates 1991) suggest that *Suncus* is retained as a matter of convenience and that the only real difference between *Suncus* and *Crociodura* is the possession of the small fourth upper unicuspid in *Suncus* – and this tooth is often vestigial. Quérrouil *et al.* (2001) suggest that, on the evidence of mtDNA data, *Suncus* originated in Africa from a *Sylvisorex*-like ancestor, perhaps 7–9 mya. Because *Sylvisorex* is endemic to Africa, it is likely that *Suncus* evolved in Africa, and later migrated to Asia. The oldest fossils of *Suncus*, from 3–5 mya, are from East and South Africa (Butler 1998), and are much older than any from Europe or Asia. The alternative view (Butler *et al.* 1989) is that *Suncus* evolved in Asia and migrated to Africa.

The species in the genus are distinguished by size, relative length of the tail, habitat and distribution.

D. C. D. Happold

Suncus aequatorius TAITA DWARF SHREW

Fr. Pachyure du Taita; Ger. Taita-Zwergspitzmaus

Suncus aequatorius (Heller, 1912). Smithsonian Misc. Coll. 60, 12: 4. Summit of Mt Sagalla, Taita Hills, Kenya.

Taxonomy Originally described as a subspecies of *Pachyura lixa* by Heller (1912) and subsequently transferred to genus *Suncus* (see Heim de Balsac & Meester 1977). Referred to as a subspecies of *S. lixus* by

Aggundey & Schlitter (1986), and as a synonym of *S. lixus* by Hutterer (1993). Now considered as a full species (Oguge *et al.* 2004, Hutterer 2005b). Synonyms: none. Chromosome number: not known.

Description Small–medium shrew with soft, smooth short pelage. Dorsal pelage grey; hairs grey at base, brown at tip. Flanks similar to dorsal pelage. Ventral pelage pale grey. Chin and throat similar in colour to ventral pelage. Head broad (greatest width similar to incisor–molar length). Muzzle pink, covered with long (18.5 mm) clear white vibrissae. Eyes small. Ears large, oval and pale, almost white and bare; held laterally and backwards from head at an oblique angle. Fore- and hindfeet each with five claws. Forelimbs below ‘elbow’ covered with short fine white hair; soles naked, toes with white claws. Hindlimbs below ‘knee’ covered with short fine white hair; conspicuous white claws. Tail thin and relatively long (ca. 78% of HB), covered by dirty whitish fine fur along its length; fine white scales ventrally, decreasing in density laterally and even more so dorsally; pilosity at least 50%. Males tend to be larger (on average) than ♀♀ (see Measurements). Nipples: not known.

Geographical Variation None recorded.

Similar Species

Suncus lixus. Dorsal pelage greyish-brown. Tail shorter (T: 36–51 mm) and relatively shorter (64% of HB), brown above, whitish or yellow below; pilosity 80–100%.

S. megalura. Head and body smaller (HB: 50–65 mm); tail much longer (T: 82–97 mm) and relatively much longer (ca. 118% of HB). Perhaps parapatric in SE Kenya.

Distribution Endemic to eastern Africa. In SE Kenya, recorded only from two locations: Mt Sagalla (1500 m; 03° 30' S, 38° 35' E), and Chawia Forest (1600 m; 03° 28' S, 38° 28' E) in the Taita Hills (Oguge *et al.* 2004). Not recorded from the other 12 of 14 locations sampled (1400–2228 m) (Oguge *et al.* 2004). Perhaps occurs in NE Tanzania (Hutterer 2005b, not mapped).

Habitat Disturbed remnant forest in highland regions (1500–1600 m), where annual rainfall is more than 1000 mm (Oguge *et al.* 2004); dominant vegetation includes *Tabernaemontana stapfiana* (tree) and *Dracaena steudner* (shrub).

Abundance Common in the highly degraded forests of Mt Sagalla, comprising 69% of captures (11 of 16 shrews captured; 4 spp.). Rare in the Dabida massif with captures only in Chawia Forest (1 of 72 shrews captured; 10 spp.) (Oguge *et al.* 2004).

Remarks Distribution is disjunct and abundance (where present) is varied. The commonest species of syntopic shrews in Chawia Forest are *Crocidura hildegardae* and *C. jacksoni* (Oguge *et al.* 2004). *Suncus aequatorius* is considerably larger than *S. lixus* (condyloincisive length 21.3 mm [cf. 19.7 mm in *S. lixus*], tail 51–67 mm [cf. 36–51 mm in *S. lixus*]; see Meester & Lambrechts 1971), and geographically separated by some 800 km from the northernmost population of *S. lixus* in the Udzungwa Mts, S Tanzania (Stanley & Hutterer 2007).

Suncus aequatorius

Conservation IUCN Category: Critically Endangered.

Reduction in the size and extent of forest fragments has probably reduced the geographic range of the species in recent years.

***Suncus etruscus* ETRUSCAN DWARF SHREW (PYGMY WHITE-TOOTHED SHREW)**

Fr. Pachyure étrusque; Ger. Etrusker-Zwergspitzmaus

Suncus etruscus (Savi, 1822). Nuovo Giorn. de Letterati, Pisa 1: 60. Pisa, Italy.

Taxonomy Originally described in the genus *Sorex*. African specimens are considered to be the nominate form. Synonyms: none in Africa (but see Hutterer 2005b for extralimital synonyms). Chromosome number: $2n = 42$, $FN = 74$, $aFN = 68$ (Meylan 1968, Catalan 1984, Zima & Kral 1984).

Description Minute shrew, one of the smallest terrestrial mammals in the world (see also *S. remyi*). Dorsal pelage greyish-brown. Ventral pelage pale grey. Long hairs scattered through pelage. Eyes small. Ears large. Snout elongated with long vibrissae. Hindfeet very small (useful character for distinguishing this species from the young of larger species). Tail of relative medium length (ca. 60% of HB), same colour as body, with some scattered long hairs. Braincase flat, interorbital region narrow; mandible gracile. Nipples; not known.

Geographic Variation None recorded in Africa.

Similar Species No other species of *Suncus* occurs in northern Africa.

Distribution Mediterranean Coastal BZ. Recorded from the Mediterranean region of N Morocco, N Algeria (reaching south to the northern limit of Hauts Plateaux) and N Tunisia. Also recorded from N Libya (Cyrenaica) and N Egypt. Altitudinal range: sea level to 1000 m. Some records outside this range can be associated with synanthropic habits, e.g. at Figuig oasis in SE Morocco, Biskra oasis in Algeria and Nefta oasis in Tunisia (not shown on map). Three records need confirmation: Sherifuri and Futuk (both in N Nigeria) and Bahar-Dar (in Ethiopia; not mapped). Extraliminally known from S Europe to the Arabian peninsula, Asia Minor, the Himalaya Mts, Thailand and Yunnan (China).

Habitat Preferred habitats include abandoned olive groves, vineyards and other cultivated areas overrun by Mediterranean shrubs, but also gardens, low maquis, scrub and open forest of Mediterranean oaks and pines provided that old dry stone walls are available as shelters. Particularly common in river banks in Tunisia (Müller 1956) and near humid habitats in Algeria (Baziz *et al.* 2002). Avoids sand dunes, dense forests and intensively cultivated land.

Abundance Much less common than other species of shrews (e.g. *Crocodyrus russula* and *C. whitakeri*) living in the same area in Algeria (as assessed by trapping and in owl pellets, e.g. 1 : 7.2; Rzebik-Kowalska 1985). In Africa, greatest abundance recorded in the coastal zone of Algeria.

Adaptations More active during the night than during the day, with a peak of activity at dawn. Exhibits daily variations of weight, hypothermy and torpor; these variations are necessary regulatory

*Suncus etruscus*

mechanisms because of the small body size, high level of activity and high energy consumption (oxygen consumption: 6 ml O_2 /g/h). A respiratory rate of up to 894 breaths/minute, and a heart rate up to 1500 beats/minute, has been recorded (Fons 1975, Fons *et al.* 1997).

Foraging and Food Captive individuals eat wild-caught invertebrates and small vertebrates. They appear to feed on any species except chemical-protected arthropods (e.g. some chilopods and Heteroptera) and insects with strong chitinous exoskeletons (e.g. some Coleoptera).

Social and Reproductive Behaviour Social interactions were observed during the breeding season. During the rest of the year, animals are solitary and aggressive. Territoriality is established by vocalizations and fights.

Reproduction and Population Structure Reproductive season in Africa uncertain, but occurs in spring to autumn (Mar–Oct) in W Europe. Gestation: 27–28 days. Litter size: 3.9 (2–5). At birth, young naked and blind; HB: 4–15 mm; WT: 0.2 g. Weaned at Day 19–21. A ♀ may have up to six litters during her life. Breeding occurs only after the winter following birth. Very few animals probably survive to breed after a second winter in the wild.

Predators, Parasites and Diseases May represent 5% of the diet of Barn Owls *Tyto alba* in the coastal zone of Algeria, and up to

10% in some locations, but only 1% further inland (Rzebiak-Kowalska 1985). Also preyed on by the Pharaoh Eagle-owl *Bubo ascalaphus*, Little Owl *Athene noctua* and occasionally by some carnivores and reptiles. Apart from some ectoparasites, four helminths have been described from this shrew.

Conservation IUCN Category: Least Concern.

Etruscan shrews are vulnerable to insecticides and herbicides.

Suncus hututsi HUTU-TUTSI DWARF SHREW

Fr. Pachyure des Hutus et Tutsis; Ger. Hutu-Tutsi Zwergspitzmaus

Suncus hututsi Kerbis Peterhans and Hutterer 2009. Bonn. Zool. Monog. 55: 144. Ruhondo, Kibira National Park, NW Burundi. 2040 m.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Very small dark shrew. Pelage very short (hairs 1–2 mm). Dorsal pelage blackish-grey. Ventral page slightly paler. Eyes tiny. Ears visible in dorsal view. Tail of relative medium length (ca. 60% of HB), dark brown above, slightly paler below; small bristle hairs; pilosity ca. 50%. Skull very small, short upper tooththrow, four upper unicusps; mandible lightly built with short tooththrow, lower first incisor without denticulations, and low coronoid process (3.0 [range 2.9–3.2] mm). (See also key in Thorn & Kerbis Peterhans 2009.) Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Similar Species

Suncus megalura. On average larger (HB: 60.8 [50–65] mm); tail much longer (T: 82–97 mm) and relatively much longer (ca. 118% of HB); skull longer (CI: 16.8–18.6 mm). Perhaps parapatric in Burundi; mostly associated with moist savanna.

S. murinus. Much larger and heavier (HB: ca. 105–155 mm, T: 50–85 mm, WT: ca. 65–105g). Geographic distribution overlaps in Burundi; only one specimen known; commensal.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the highlands on the east side of the Albertine Rift Valley. Recorded from Burundi (Kibira N. P.) and Uganda (Bwindi-Impenetrable N. P., Mujuzi F. R. and Kasana Kasambya F. R.; Kasangaki *et al.* 2003). Altitude range: 1170–2350 m.

Habitat Well-drained closed-canopy montane forest amidst *Dombeya joatizen* (holotype). Also recorded in upland bamboo (*Arundinaria alpina*) with mixed hardwoods, amongst forbs, sedges, grasses and *Begonia* sp. (Burundi), on the edge of a swamp beneath *Laconia* sp. (Bwindi-Impenetrable N. P., Uganda), and on dry forested slopes (Kasana Kasambya F. R., Uganda).

Abundance Extremely rare in collections, known at present by only 14 specimens. Its (apparent) rarity may be because it is very difficult to capture such a very small shrew. All known captures are from pitfall traps, a relatively recent innovation for surveys of small mammals in Africa.

Remarks Nocturnal. Although a rare species, a ♂ and ♀ have been collected in the same trapline, although not at the same time. Stomach contents (n = 3) include spiders (Araneae) and immature and adult Coleoptera (J. Boone in litt.). Ectoparasites include ticks of the families Ixodidae (larvae, on head), Trombiculidae (on ear pinnae, tail and back), Laelapidae (on back) and Glycyphagidae (on face and back) (B. O'Connor in litt.).

Suncus hututsi

Conservation IUCN Category: Vulnerable.

This species is threatened because of its rarity and very restricted geographic range; in this respect it is similar to other endemic species of the Albertine Rift Valley.

Suncus infinitesimus LEAST DWARF SHREW

Fr. Pachyure de Heller; Ger. Kleinere Zwergspitzmaus

Suncus infinitesimus (Heller, 1912). *Smithson. Misc. Coll.* 60 (12): 5. Rumruti, Laikipia Plateau, Kenya. 7000 ft (2135 m).

Taxonomy Originally described as *Pachyura infinitesimus*. Polytypic with three geographically widely separated forms. Hutterer (2005a) lists these forms as synonyms, but their status is uncertain. Clusters genetically with *Suncus remyi*, and may also be related to the widely distributed species *S. etruscus* (Quéroutil *et al.* 2001). Synonyms: *chriseos*, *ubangiensis*. Subspecies: none. Chromosome number: not known.

Description Very small shrew. Dorsal pelage darkish grey-brown; hairs dark slaty-grey at base, narrow white subterminal band, brown at tip. Ventral pelage grey; hairs dark slaty-grey at base, white at tip. Colours of dorsal and ventral pelage merge gradually. Head slender with long, narrow pointed muzzle. Eyes small. Ears rounded. Fore- and hindfeet greyish-brown. Tail of medium relative length (ca. 55% of HB), brown above, paler below. Nipples: 0 + 3 = 6.

Geographic Variation Three forms have been described (see Heim de Balsac & Meester 1977):

chriseos: South Africa: (Eastern Cape, Gauteng, KwaZulu–Natal,

North West and Free State Provinces) and Swaziland (Malolotja).

infinitesimus: Kenya and perhaps Uganda.

ubangiensis: Central African Republic (Bangui) and Cameroon.

Similar Species

Suncus megalura. Tail much longer (T: 82–97 mm) and relatively much longer (ca. 118% of HB). Skull longer (CI: 16.8–18.6 mm). Dorsal and ventral colours merge. Geographic distribution overlaps in Central African Republic, SW Kenya, and perhaps Cameroon.

S. varilla. Dorsal pelage greyish-chestnut; ventral pelage whitish-grey; colours of dorsal and ventral pelage clearly delineated. Geographic distribution overlaps in some areas of South Africa.

Distribution Endemic to Africa. Distribution disjunct. Primarily Coastal Forest Mosaic BZ of South Africa and adjacent Afromontane–Afroalpine and South-West Cape BZs (plus scattered records in savanna zones further north). Recorded from three well-separated areas: (a) South Africa (Gauteng, North West and Free State Provinces, coastal regions of the Eastern Cape Province) (Meester

& Lambrechts 1971, Skinner & Smithers 1990), KwaZulu–Natal (Taylor, P. 1998) and W Swaziland (Monadjem 1998a, c); (b) Kenya (Aggundey & Schlitter 1986); (c) Central African Republic (Petter & Chippaux 1962) and Cameroon (Hutterer & Joger 1982).

Habitat Primary forest, montane grassland, savanna and mixed bushveld. In South Africa, commonly associated with disused termitaria of the snouted harvester termite *Trinervitermes trinervoides* (Lynch 1983).

Abundance Uncommon. Probably more abundant than indicated by surveys. Fairly widespread in the lower-lying regions of central and eastern KwaZulu–Natal (Taylor, P. 1998).

Adaptations These tiny shrews are able to reduce their costs of metabolism by making use of termitaria, where the microclimate is mild and comparatively stable. They might also utilize torpor, a

Suncus infinitesimus

characteristic of crocidurines (Taylor, J.R.E. 1998). Ball-shaped nests (100 mm diam.) are constructed in the termitaria (Lynch 1983).

Foraging and Food Insectivorous. Readily eats beetles in captivity.

Social and Reproductive Behaviour Usually solitary (Rautenbach 1982). Mating behaviour involves nose-to-tail chasing culminating in a brief copulation (R. M. Baxter pers. obs.).

Reproduction and Population Structure Appears to be reproductively active during the wet season (Lynch 1983, Taylor, P. 1998). Litter size probably 2–3 (Taylor, P. 1998).

Predators, Parasites and Diseases Preyed on by owls, occasionally caught by domestic cats and dogs (Dippenaar 1997).

Conservation IUCN Category: Least Concern.

Suncus lixus GREATER DWARF SHREW

Fr. Pachyure de Thomas; Ger. Größere Zwergspitzmaus

Suncus lixus (Thomas, 1898). Proc. Zool. Soc. Lond. 1897: 930. Nyika Plateau, Malawi.

Taxonomy Originally described in the genus *Crociodura*. The form *aequatorius* was included formerly with *S. lixus* (e.g. Heim de Balsac & Meester 1977, Hutterer 1993). In contrast, Hutterer (2005a) treats *aequatorius* as a full species with a geographic range in SE Kenya and N Tanzania (see below). Synonym: *gratulus*. Subspecies: none. Chromosome number: not known.

Description Small shrew with a moderately long tail. Dorsal pelage greyish-brown. Ventral pelage pale grey. Colours of dorsal and ventral pelage merge gradually on flanks. Head slender with long, narrow pointed muzzle. Eyes small; ears rounded. Fore- and hindfeet whitish. Tail moderately long (ca. 64% of HB), brown above, whitish or yellow below; pilosity 80–100% (Meester & Lambrechts 1971). Nipples: 0 + 3 = 6.

Geographic Variation Heim de Balsac & Meester (1977) listed three forms:

lixus: N Botswana, Zambia, Malawi and Tanzania.

gratulus: South Africa.

(*aequatorius*: now considered to be a separate species [see *Suncus aequatorius*])

Similar Species

Suncus aequatorius. Dorsal pelage grey. Tail longer (T: 53–67 mm) and relatively longer (ca. 78% of HB), covered by dirty whitish, fine fur along its length, pilosity at least 50%. Kenya only.

S. megalura. Tail much longer (T: 82–97 mm) and relatively much longer (ca. 118% of HB). Geographic distribution overlaps in S DR Congo, Zambia, SW Tanzania and E Angola.

S. varilla. Colours of dorsal and ventral pelage clearly delineated. Skull shorter (CI: 15.1–17.0 mm). Geographic distribution overlaps or almost overlaps in S DR Congo, NE Zambia, Zimbabwe and N South Africa.

Distribution Endemic to Africa. Widely distributed mainly in the Zambezan Woodland BZ and southern part of the Somalia–

Suncus lixus

Masai Bushland BZ. Recorded from NE Angola, S DR Congo, S Tanzania, W Zambia, N Malawi, N Botswana, Zimbabwe, SW Mozambique, N South Africa and Swaziland. In South Africa, occurs widely in eastern parts of Limpopo Province (with a south-westerly extension into North West Province), Mpumalanga Province and the lower-lying areas of KwaZulu–Natal Province (Meester & Lambrechts 1971, Heim de Balsac & Meester 1977, Wirminghaus & Nanni 1989, Skinner & Smithers 1990, Monadjem 1998a, c, Taylor, P. 1998).

Habitat Moist riverine forest, coastal lowland forest, savanna woodland, thornveld, semi-arid scrub and grassland. Capable of living in a wide range of vegetation types.

Abundance Uncommon. Probably more abundant than indicated by surveys. In most of the countries listed above, known only from very few specimens from scattered localities.

Remarks Known to inhabit termite mounds. Might utilize torpor, a characteristic of crocidurines (Taylor, J. R. E. 1998). Insectivorous. In South Africa, reproductive activity recorded in the wet season (Jan), but a lactating ♀ has been reported in Aug from KwaZulu–

Natal (Wirminghaus & Nanni 1989). Litter size: three. Preyed on by Barn Owls (Vernon 1972).

Conservation IUCN Category: Least Concern.

Suncus megalura CLIMBING DWARF SHREW

Fr. Pachyure grimpeuse; Ger. Kletter-Zwergspitzmaus

Suncus megalura (Jentink, 1888). Notes Leyden Mus. 10: 48. Schlieffelinsville, Junk R., Liberia.

Taxonomy Originally described in the genus *Pachyura*. Formerly considered to be a species of *Sylvisorex*, but genetic data (Quérroul *et al.* 2001) suggest that it should be allocated to the genus *Suncus*. Synonyms: as listed below. Subspecies: none. Chromosome number: 2n = 48 (Côte d'Ivoire; Meylan 1975).

Description Small shrew with an extremely long, thin tail and long hindfeet. Pelage soft and moderately dense; dorsal hairs 5 mm. Dorsal pelage greyish with brown tinge; hairs grey on basal two-thirds, brown on terminal third. Ventral pelage off-white to pale-buffy; hairs grey, with white or buff tip. Flanks similar to dorsal pelage or grey; colours of flanks and ventral pelage merge. Head slender with long, narrow pointed muzzle, small eyes and rounded ears. Fore- and hindfeet brown, slender and relatively long (ca. 25% of HB). Tail relatively extremely long (ca. 118% of HB), dark brown above, pale buffy below; ringed with small scales and covered with minute dark bristles. Nipples: 0 + 3 = 6.

Geographic Variation Seven forms (listed as subspecies by Heim de Balsac & Meester 1977) are recognized (see also Hutterer 2005b):

angolensis: Angola, NW Zambia.

gemmeus: Kenya, Uganda, NE DR Congo, Rwanda.

infuscus: Cameroon, Gabon, Central African Republic.

megalura: Guinea, Liberia, Côte d'Ivoire.

phaeopus: Ethiopia.

sheppardi: Zimbabwe, W Mozambique.

sorella: Mozambique (northern Tete district)

Similar Species

Suncus aequatorius. Head and body larger (HB: 66–85 mm); tail much shorter (T: 51–67 mm); and relatively much shorter (ca. 78% of HB). Perhaps parapatric in SE Kenya.

S. hututsi. On average smaller (HB: 52.6 [44–58] mm); tail much shorter (T: 28–33 mm) and relatively much shorter (ca. 60% of HB); skull shorter (CI: 13.3–14.2 mm). Perhaps parapatric in Burundi. Montane forest and upland bamboo.

S. infinitesimus. Tail much shorter (T: 23–31 mm) and relatively much shorter (ca. 55% of HB). Skull shorter (CI: 13.9–15.2 mm). Dorsal and ventral colours sharply delineated. Geographic distribution overlaps in Central African Republic, SW Kenya, and perhaps Cameroon.

S. lixus. Tail much shorter (T: 36–51 mm) and relatively much shorter (ca. 64% of HB). Geographic distribution overlaps in S DR Congo, SW Tanzania, Zambia and E Angola.

S. murinus. Much larger and heavier (HB: ca. 105–115 mm, WT: ca. 65–105g). Geographic distribution overlaps in Rwanda and Tanzania but *S. murinus* is commensal.

S. remyi. Smaller (HB: 42–48 mm); tail much shorter (T: 17–21 mm) and relatively much shorter (ca. 41% of HB). Apparently allopatric but geographic distribution fairly close in Cameroon, Gabon and Congo.

S. varilla. Colours of dorsal and ventral pelage clearly delineated. Tail much shorter (T: 25–45 mm) and relatively much shorter (ca. 60% of HB). Geographic distribution overlaps or almost overlaps in S DR Congo, W Tanzania, N Zambia, Malawi, N Zimbabwe and C Mozambique.

Distribution Endemic to Africa. Widespread, but apparently disjunct in many biotic zones: Rainforest BZ of West Africa, Rainforest–Savanna Mosaics and parts of Zambezian Woodland BZ. Not recorded in the Rainforest BZ of central Africa. Recorded from West, central and East Africa and southwards into E Zimbabwe, C Mozambique and Angola. The southern extension has an annual rainfall of 800–1200 mm (Smithers & Lobão Tello 1976, Heim de Balsac & Meester 1977, Ansell 1978, Smithers & Wilson 1979, Ansell & Dowsett 1988).

Habitat Very varied, and mostly associated with moist savanna. In Zimbabwe, recorded in thick scrub and on the fringe of an orchard near tall grass (Smithers 1983). In Zambia, found in tall grass of a drying stream bed (Ansell 1960a). In Kivu Province, DR Congo, captured in regenerating bush (30 specimens), long elephant grass (13) and in grassy scrub (11) (Dieterlen & Heim de Balsac 1979). Most specimens captured between 1600 m and 1900 m; relatively uncommon at higher altitudes.

Abundance One of the rarest species of shrew in Taï N. P. (Côte d'Ivoire), representing only 0.25% (n = 390 shrews; 9 spp.) in forest, and 0% in cocoa–coffee plantations (n = 140; 7 spp.) (Barrière *et al.* 1999). In Ziama Biosphere Reserve (Guinea), abundance varied according to habitat: 26.5% (n = 272 shrews; 9 spp.) in fields where it was the commonest species, 5.2% (n = 303; 10 spp.) in young forest plantations, 4.13% (n = 484; 9 spp.) in old fallow land, 2.7% (n = 441; 9 spp.) in old forest plantations, 1.6% (n = 500; 11 spp.) in primary forest and 0% (n = 509; 10 spp.) in secondary forest (P. Barrière unpubl.).

Adaptations The long tail is prehensile and used extensively in climbing. When stretching towards a distant branch, can support itself using its tail and relatively large hindfeet. In captivity, captures grasshoppers above the ground (Vogel 1974).

Foraging and Food Insectivorous. In Taï N. P. (Côte d'Ivoire), this species (as *Sylvisorex megalura*) was the only species of shrew that ate centipedes (Chilopoda) (n = 1 stomach; Churchfield *et al.* 2004).

Social and Reproductive Behaviour A single nest in Zimbabwe was spherical and constructed of broadleaf grasses; it was situated 1 m above ground in the branches of a bush (Dieterlen & Heim de Balsac 1979).

Reproduction and Population Structure Eight of 15 females collected in Mar (1 specimen), Jun (3), Aug (1) and Nov (3) in Kivu Province, E DR Congo, were reproductively active. Litter size: 1.8 (no range), mode 2, n = 5 (Dieterlen & Heim de Balsac 1979).

Suncus megalura

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.
Widely distributed; survives well in disturbed habitats.

Measurements

Suncus megalura

HB: 60.8 (50–65) mm, n = 36

T: 88.8 (82–97) mm, n = 36

R. M. Baxter & N. J. Dippenaar

Suncus murinus ASIAN HOUSE SHREW

Fr. Musaraigne asiatique des maisons (Pachyure musquée); Ger. Hausspitzmaus

Suncus murinus (Linnaeus, 1766). Syst. Nat., 12th Ed., 1: 74. Java, Indonesia.

Taxonomy Originally described in the genus *Sorex*. Very variable species with a number of genetically distinct populations (Hutterer 2005b). Many synonyms, mostly extralimital to Africa (see Hutterer

2005b for full details). Synonyms (Africa only): *albicauda*, *auriculata*, *crassicaudus*, *duvernoyi*, *geoffroyi*, *leucura*, *mauritiana*, *sacer*. See also Hutterer & Tranier (1990) and Heim de Balsac & Meester (1977).

Subspecies: none. Chromosome number: $2n = 40$ (Djibouti; E. Pequignot in Hutterer & Tranier 1990).

Description Very large, rat-sized shrew. Dorsal pelage greyish-brown. Ventral pelage paler, no clear delimitation between dorsal and ventral pelage. Cutaneous scent-gland situated behind the shoulder, present in both sexes. Ears short and rounded. Palms and soles naked. Tail relatively long (ca. 63% of HB), thick. Four upper unicuspid; the fourth very small – much smaller than the third. Nipples: $0 + 3 = 6$.

Geographic Variation None recorded.

Similar Species

Suncus hututsi. Much smaller and lighter (HB: 44–58 mm, T: 28–33 mm, WT: ca. 1.7–2.4 g). Geographic distribution overlaps in Burundi; montane forest.

S. megalura. Much smaller and lighter (HB: 50–65 mm, WT: 3–8 g). Geographic distribution overlaps in Rwanda and Tanzania but *S. megalura* is not commensal.

Distribution Introduced recently into Africa (Hutterer & Tranier 1990). First recorded in Egypt during the eighteenth century, but no other records since then and now probably locally extinct (Osborne & Helmy 1980). Also recorded from Sudan (one record, Hutterer & Tranier 1990), Eritrea (one; Hutterer & Tranier 1990), Djibouti (two; Hutterer & Tranier 1990, Pearch *et al.* 2001), Kenya (two; Schlitter & Aggundey 1986), Tanzania (five; Hutterer & Tranier 1990) and Rwanda (one; Hutterer *et al.* 1987). Pemba and Zanzibar Is (Hutterer & Tranier 1990). With exception of specimens from Rwanda and Tanzania, found only in harbours. Extraliminally widespread from Burma and Afghanistan to China and throughout most of South-East Asia, including the Philippines and Japan; Madagascar and some islands of the Indian Ocean (Hutterer 2005b).

Habitat Commensal in Africa, but also lives in natural habitats in Asia (Nowak 1999).

Abundance There is no evidence that any population is firmly established on mainland Africa. All records refer to very few individuals. Present for only a short period (mostly before 1920, although one individual found in Djibouti in 1999 [Pearch *et al.* 2001]). It seems that individuals are introduced from time to time, and survive (breed?) within harbours before becoming locally extinct; a few reached further inland on transport routes.

Remarks Nocturnal. There is no information on the species in Africa. Elsewhere (Nowak 1999 and references therein), the diet is insectivorous plus items of human food and refuse. Individuals are

Suncus murinus

solitary and intolerant of one another. Gestation: 30 days. Litter size: 2.1 (1–4) on Guam Island; 2.8 (1–6) on Madagascar. Weaned at Day 17–20 (Hasler *et al.* 1997).

Conservation IUCN Category: Least Concern.

Numerous strains maintained in captivity. Extensively used as a laboratory animal, mainly for physiological studies (Oda *et al.* 1980). Regarded as a pest when population numbers are large.

***Suncus remyi* REMY'S DWARF SHREW (REMY'S PYGMY SHREW)**

Fr. Pachyure de Remy; Ger. Remys Zwergspitzmaus

Suncus remyi Brosset, Dubost and Heim de Balsac, 1965. Biologia Gabonica 1: 170. Makokou, Gabon.

Taxonomy Genetically related to *S. infinitesimus* (Quéroutil *et al.* 2001). Synonyms: none. Chromosome number: not known.

Description Minute shrew, one of the smallest of all shrews. Pelage fine, short and dense. Dorsal pelage rich reddish-brown to rufous-brown; hairs grey on basal third, rich reddish-brown on terminal two-thirds. Ventral pelage slightly paler than dorsal pelage. Ears small and naked, clearly visible, not concealed by pelage. Fore- and hindfeet dark reddish-brown, with small claws. Tail relatively short or of medium length (ca. 41% of HB), dark brown; small dark hairs on basal 50–80%. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Suncus megalura. Larger (HB: 50–65 mm); tail much longer (T: 82–97 mm) and relatively much longer (ca. 118% of HB). Apparently allopatric but geographic distribution fairly close in Cameroon, Gabon and Congo.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Gabon sub-region]). Recorded from N Gabon, Congo and SW Central African Republic.

Habitat In Gabon, found in a variety of habitats: primary rainforest especially where moist, and secondary marshy forest (Brosset *et al.* 1965b, Brosset 1988), and in heterogeneous and homogeneous rainforest (Goodman *et al.* 2001).

Abundance Uncommon or rare. Comprised 11% (2 of 18; 10 spp.) in two habitats at Minkébe Forest, Gabon (Goodman *et al.* 2001); 6% (1 of 16; 8 spp.) in one habitat at 110 m on Mt Doudou (Goodman & Hutterer 2004); 5% (8 of 160; 11 spp.) at Belinga and Makokou (Brosset 1988); and only 1% (5 of 503; 9 spp.) at another site on Mt Doudou (Nicolas *et al.* 2004). It has not been encountered at other study sites where shrews have been captured.

Remarks Embryo number: 1, n = 3 (Brosset 1988). One ♀ caught in Aug contained one full-term embryo; no information for other months (Brosset *et al.* 1965b).

Suncus remyi

Conservation IUCN Category: Least Concern.

***Suncus varilla* LESSER DWARF SHREW**

Fr. Pachyure petite; Ger. Zierliche Zwergspitzmaus

Suncus varilla (Thomas, 1895). Ann. Mag. Nat. Hist., ser. 6, 16: 54. East London, Cape Province, South Africa.

Taxonomy Originally described as *Crocidura (Pachyura) varilla*. Heim de Balsac & Meester (1977) list five subspecies, and Hutterer (2005a) lists six synonyms (as given here). Synonyms: *meesteri*,

minor, *natalensis*, *orangiae*, *tulbaghensis*, *warreni*. Subspecies: none. Chromosome number: not known.

Description Very small shrew with a long tail. Dorsal pelage greyish-chestnut; hairs pale slaty-grey at base, silvery-white sub-terminal band, buffy-brown at tip. Ventral pelage whitish-grey; hairs pale slaty-grey at base, with broad white to fawn tip. Colour of dorsal and ventral pelage clearly delineated. Head slender with long, narrow pointed muzzle. Eyes small, ears rounded. Fore- and hindfeet white. Tail relatively long (ca. 60% of HB), brown above, paler below, with numerous long bristles over its length. Nipples: not known.

Geographic Variation Heim de Balsac & Meester (1977) listed five forms, without comment:

minor: DR Congo and Tanzania.

orangiae: NE Zimbabwe, Malawi (?); C Mozambique, South Africa (North West, Gauteng, Free State, NE Eastern Cape and KwaZulu–Natal Provinces).

tulbaghensis: South Africa (limited parts of Western Cape Province).

varilla: South Africa (East London in Eastern Cape Province).

warreni: South Africa (from Port Nolloth in Northern Cape Province to van Rhynsdorp in Western Cape Province).

Similar Species

Suncus infinitesimus. Dorsal pelage darkish grey-brown; ventral pelage grey; colours of dorsal and ventral pelage merge gradually. Geographic distribution overlaps in some areas of South Africa.

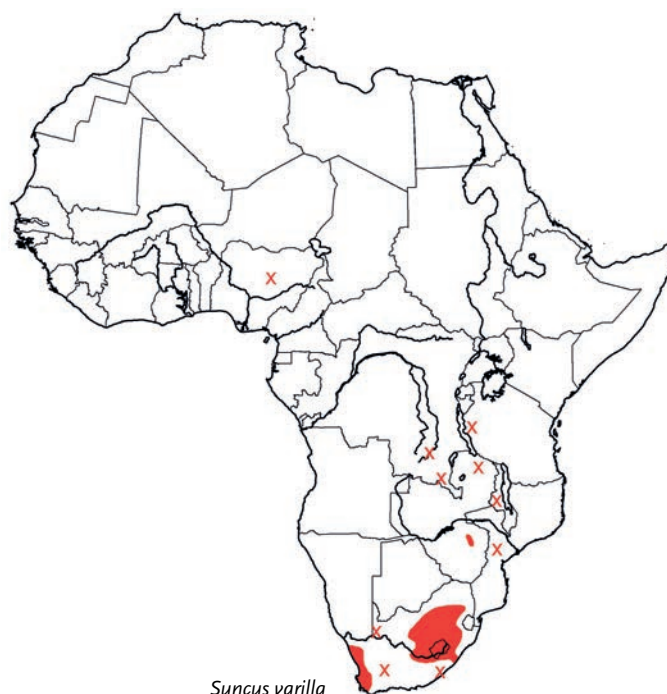

S. lixus. Colours of dorsal and ventral pelage merge. Skull longer (CI: 19.2–20.7 mm). Geographic distribution overlaps or almost overlaps in S DR Congo, NE Zambia, Zimbabwe and N South Africa.

S. megalura. Colours of flanks and ventral pelage merge. Tail much longer (T: 82–97 mm) and relatively much longer (ca. 118% of HB). Geographic distribution overlaps or almost overlaps in S DR Congo, W Tanzania, N Zambia, Malawi, N Zimbabwe and C Mozambique.

Distribution Endemic to Africa. Zambezan Woodland BZ, and parts of the Highveld and South-West Cape BZs. Recorded from DR Congo, W Tanzania, NE Zambia, Malawi, NE Zimbabwe, C Mozambique and South Africa. Records are widely separated and disjunct, especially in the north of the geographical range. One isolated record (skull fragments from an owl pellet) from N Nigeria (see Hutterer & Happold 1983).

Habitat Occurs in a great variety of vegetation types. In South Africa, usually recorded in grassland habitats, and often (but not always) associated with the termitaria of Harvester Termites *Trinervitermes trinervoides*. In KwaZulu–Natal also found in piles of wood, suburban gardens, open savanna and on the secondary margins of coastal forests (Taylor, P. 1998). Appears to be dependent on the disused mounds of these termites, in which it constructs spherical nests of grass (Lynch 1983, 1986). No information about habitat in northern part of range.

Abundance Widespread in South Africa, but mostly uncommon. Thirty specimens were collected from 27 localities throughout Free State Province (Lynch 1983) and 15 specimens were collected from

Suncus varilla

ten localities in (former) Transvaal (Rautenbach 1982). Densities of 0.25–8 individuals/ha recorded in central Free State Province of South Africa (Lynch 1991).

Adaptations Spherical nests are built in termite mounds, mostly in the centre or oriented towards the north or west (the warmer sides) of the mound, and mostly below ground level (Lynch 1985). The close association with termite mounds provides a thermally stable and insulated micro-habitat, which reduces the cost of thermoregulation and expenditure of energy. This very small shrew enters torpor, as do other crocidurines (Taylor, J. R. E. 1998), as a means to further reduce energy expenditure.

Foraging and Food Insectivorous. In captivity, feeds on grasshoppers, crickets, termites and ox-liver (Taylor, P. 1998).

Social and Reproductive Behaviour Thought to be monogamous, with 65% of adults occurring in pairs, regardless of the time of year. Young animals accompany ♀♀ for up to nine months. Parental care is well developed. Caravanning has been observed (Lynch 1985). Young leave the ♀ in the dry season (ca. May), and pair before breeding commences in Aug (Lynch 1990, 1991).

Reproduction and Population Structure In Free State Province, South Africa, pregnancies recorded during late dry season (Aug–Sep) and the wet season (Oct–Mar), but mostly in Aug–Nov. Embryo number: 3.7 (2–7). Litter size: 3.3 (2–7). There is no noticeable die-off, with 92% of population comprising adults during the dry season (May–Jul). By end of the wet season, 42% of population comprises juveniles or subadults. Longevity is estimated at 24–30 months during which time females produce 2–3 litters. A postpartum oestrus occurs, but only 18% of ♀♀ produce a second litter in a breeding season. Most ♀♀ do not breed during the season of birth (Lynch 1990, 1991).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

A widely distributed species that is not threatened at present.

GENUS *Surdisorex*

Mole-shrews

Surdisorex Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 223. Type species: *Surdisorex norae* Thomas, 1906.

The genus *Surdisorex* contains two species, both of which live only in the highlands of Kenya. The distinguishing characters of *Surdisorex* are the absence of external ears, enlarged forelimbs and claws, very short tail (ca. 30% of HB), large elongated skull (24–27 mm), and wide braincase (GWS 50–55% of CI; other genera <50% of CI). There are three unicuspid teeth in each upper jaw (as in *Congosorex*; Figure 20; see also Table 7). In all these respects, *Surdisorex* differs from the genus *Myosorex* to which it is closely related. Both species of the genus look more like small moles (family Talpidae) or golden-moles (family Chrysochloridae) than like shrews. They show some similarity in their ecology to moles, and hence have the common name of mole-shrews. The genus was formerly included in *Myosorex* but retained as a full genus by Hollister (1918), Meester (1953), Heim de Balsac (1966), Hutterer (1993) and Hutterer *et al.* (2001). Genetic and molecular data are not yet available (the genus was not included in the analysis of Quérrouil *et al.* 2001), but morphological characters support the view that the genus belongs to the Myosoricinae, as defined by Hutterer *et al.* (2001). The two species are rather similar and may be distinguished on the basis of size and geographic distribution.

Figure 20. Skull and mandible of *Surdisorex polulus* (BMNH 74.650).

Surdisorex norae ABERDARE MOLE-SHREW

Fr. Musaraigne des Aberdares; Ger. Aberdare-Wühlspitzmaus

Surdisorex norae Thomas, 1906. Ann. Mag. Nat. Hist., ser 7, 18: 223. East side of Aberdare Range, near Nyeri, Kenya.

Taxonomy Heim de Balsac & Meester (1977) and Aggundey & Schlitter (1986) refer to this species as *Myosorex (Surdisorex) norae*. Following Thomas (1906b) and Hutterer (1993, 2005a), the species is retained in the genus *Surdisorex*. Synonyms: none. Chromosome number: not known.

Description Large mole-like shrew with long claws on forelimbs, and short tail. Pelage thick and dense, with the texture of velvet. Dorsal and ventral pelage dark chocolate-brown, hairs 6–7 mm, with long black guard hairs on rump. Head broad with

pointed muzzle. Eyes very small, almost vestigial and hidden by pelage. External ears very short, just a raised area of skin around auditory meatus; not visible unless hair is displaced. Forelimbs short. Forefeet broad with five digits: Digits 3, 4 and 5 long, with long pale claws 4–6 mm; Digits 1 and 5 shorter, reaching only to level of first phalanges of other digits; claws 2–3 mm. Hindlimbs short; hindfeet short, five digits with pale claws. Tail short (ca. 30% of HB), black, covered with dense short black bristles. Skull: condyloincisive length 26–27 mm (Heim de Balsac & Meester 1977). Nipples: 0 + 3 = 6.

Geographic Variation None recorded.

Similar Species

Surdisorex polulus. Lighter (WT: 18.3 [16–21] g). Mt Kenya only.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the Aberdare Range, C Kenya. The few known specimens were collected at 2820–3300 m. The geographic distribution is probably limited by soil texture and the abundance of earthworms (see below).

Habitat Swamps in moorlands in the Aberdare highlands (Duncan & Wrangham 1971).

Abundance Very rare, known by only a few specimens.

Adaptations Nocturnal and diurnal. The forelimbs are broad with long digits and claws, and the skull is shorter, broader and stronger compared with the skulls of closely related shrews. Similar adaptations are seen in moles (Talpidae) and in golden-moles (Chrysochloridae). Mole-shrews forage and travel along runways on the soil surface, under grass and under leaf-litter. Sympatric species, which also use the runways, include *Crocidura* spp., *Sylvisorex granti*, *Lophuromys flavopunctatus*, *Mus* sp., *Praomys jacksoni*, *Hylomyscus? denniae* and *Otomys tropicalis* (Duncan & Wrangham 1971). It seems unlikely that mole-shrews excavate subterranean burrows, as do talpid moles. The mole-like characteristics of Aberdare Mole-shrews indicate that they are the ecological equivalent to moles (Talpidae) of the Palearctic, and to *Chrysochloris stuhlmanni* (Chrysochloridae), which also occurs in other East African highlands (but not sympatrically with *S. norae* in the Aberdares).

Foraging and Food Carnivorous. The diet is mainly earthworms, which are bitten into small pieces before swallowing. Small vertical holes, 1–2 cm in diameter, found in the swamps are probably made by the mole-shrews while foraging for worms (Duncan & Wrangham 1971).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Embryo number: 2 ($n = 1$). One pregnant ♀ was recorded in October (Hollister 1918). No information for other months.

Predators, Parasites and Diseases No information.

Surdisorex norae

Conservation IUCN Category: Vulnerable.

The very small geographical range, small and fragmented populations, and limited probability of recolonization (if locally extinct) are causes for concern. Habitat conservation, especially where populations are within the borders of a National Park, is essential.

Surdisorex polulus MOUNT KENYA MOLE-SHREW

Fr. Musaraigne du Mont Kenya; Ger. Mount Kenya Wühlspitzmaus

Surdisorex polulus Hollister, 1916. Smithsonian Misc. Coll. 66 (1): 1. West side of Mount Kenya, Kenya. 10,731 ft (3261 m).

Taxonomy Heim de Balsac & Meester (1977) and Aggundey & Schlitter (1986) refer to this species as *Myosorex (Surdisorex) polulus*, and Heim de Balsac & Meester (1977) suggest that it may be no more than a subspecies of *S. norae*. Following Hutterer (1993, 2005a), the species is retained in the genus *Surdisorex*. Synonyms: none.

Chromosome number: not known.

Description Large mole-like shrew with long claws on forelimbs, and short tail, very similar to *Surdisorex norae* (see Description of *S. norae*). Pelage thick and dense, with the texture

of velvet. Dorsal pelage dark chocolate-brown; hairs 5–6 mm, dark grey at base, chocolate-brown at tip; long black guard hairs on rump. Ventral pelage paler, sometimes with russet tinge. Head broad with pointed muzzle. Eyes very small, almost vestigial and hidden by pelage. No external ears, or with only a small raised area of skin on posterior margin of meatus. Forelimbs short. Forefeet broad with five digits: Digits 3, 4 and 5 long, with long pale claws 4–6 mm; Digits 1 and 5 shorter reaching only to level of first phalanges of other digits, claws 2–3 mm. Hindlimbs short; hindfeet short; five digits with pale claws. Tail relatively short (ca. 30% of HB), black, covered with dense short black bristles. Skull: condyloincisive length 24–25 mm (Heim de Balsac & Meester 1977). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Surdisorex norae. Heavier (WT: 25.0 [22.5–27.5] g). Aberdare Range, Kenya.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Only recorded from the west side of Mount Kenya at altitudes of about 10,000 ft (3300 m). As for *S. norae*, the geographic distribution is probably limited by soil texture and the abundance of earthworms.

Habitat *Podocarpus*-bamboo forests and swamps near the forests, often where there is a ground layer of short grasses and/or leaf litter.

Abundance Rare or very rare; although may be not uncommon in favoured habitats.

Adaptations Similar to *S. norae*.

Foraging and Food Carnivorous. The diet is mainly earthworms, which are bitten into small pieces before swallowing. In captivity, mole-shrews use their forefeet to hold earthworms on the ground. Usually the earthworm is eaten, starting at the anterior end, only as far as the clitellum; hence the long intestine (full of soil and detritus) is not ingested. Thereafter another worm is seized and eaten in the same way (Duncan & Wrangham 1971).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Embryo number: 1 (n = 1) and 2 (n = 1), late Aug (BMNH), Oct (Hollister 1918); no data for other months.

Surdisorex polulus

Predators, Parasites and Diseases One species of flea, *Ctenophthalmus c. cophurus*, has been recorded; this species is also found on the sympatric golden-mole *Chrysochloris stuhlmanni* (Duncan & Wrangham 1971).

Conservation IUCN Category: Vulnerable.

The very small geographical range, small and fragmented populations, and very limited probability of recolonization (if locally extinct) are cause for concern. Habitat conservation, especially where populations are within the borders of a National Park, is essential.

GENUS *Sylvisorex*

Forest Shrews

Sylvisorex Thomas, 1904. Abstr. Proc. Zool. Soc. Lond. 1904 (10): 12. Type species: *Crociodura morio* Gray, 1862.

The genus *Sylvisorex* contains 12 species distributed from SE Nigeria to NE Tanzania. All species live in primary and secondary forest habitats, and are called 'Forest Shrews' or 'Forest Musk Shrews'.

Shrews of the genus *Sylvisorex* are small to medium-sized and terrestrial. Tail length varies from short (*S. johnstoni*; mean 32 mm) to long (*S. vulcanorum*; mean 67 mm). Hindfeet are small and narrow, without special adaptations (Table 7). Ear pinnae are large and well visible. Eyes are small, as in most shrews. The pelage of most species in the genus is uniformly dark brown to blackish-brown, and only one species (*S. pluvialis*) has a whitish-grey ventral pelage. The narrow and sometimes elongated rostrum, and the round and highly domed braincase, are characteristic. The incisors and unicuspid teeth are weak; four unicuspid teeth are present in each upper jaw (Figure 21).

Biological details of any species are hardly known. *Sylvisorex johnstoni* is common in the lowland forest of the Congo Basin and may be the most numerous species in some shrew communities (Nicolas *et al.* 2003). Up to four species of the genus have been found to occur sympatrically in the lowland forests of Central African Republic (Ray & Hutterer 1995). Although most species are terrestrial, *S. vulcanorum* is sometimes scansorial.

The genus was regarded as part of *Suncus* by Smithers & Lobão Tello (1976), but was retained as a valid species by Ansell (1978). Quéroutil *et al.* (2001) studied 16s rRNA sequences of four species and found the genus, as currently understood, to be polyphyletic. As a consequence, *S. megalura* is now excluded from *Sylvisorex* and included in *Suncus*. Further taxonomic research will require a careful analysis of all taxa. Heim de Balsac (1968d) and Jenkins (1984) figured and discussed most of the species in the genus. Maddalena & Ruedi (1994) and Schlitter *et al.* (1999) described karyotypes of five species.

Figure 21. Skull and mandible of *Sylvisorex granti* (BMNH 88.55).

The 12 species recognized at present are not easily distinguished. Helpful characters and measurements are provided by Jenkins (1984), Hutterer and Schlitter (1996) and Ray & Hutterer (1996).

Rainer Hutterer

Sylvisorex camerunensis CAMEROONIAN FOREST SHREW

Fr. Musaraigne sylvestre du Cameroun; Ger. Kamerun-Waldmoschusspitzmaus

Sylvisorex camerunensis Heim de Balsac, 1968. Bonn. Zool. Beitr. 19: 35. L. Manengouba, Cameroon. 1800 m.

Taxonomy Originally described as a subspecies of *Sylvisorex granti* but now considered as a full species (Hutterer *et al.* 1992b). Synonyms: none. Chromosome number: not known.

Description Very small dark brown shrew. Pelage soft, dense and shiny; hairs ca. 6 mm on back. Dorsal pelage dark brown; hairs dark grey; dark brown at tip. Ventral pelage similar to dorsal pelage, or a little paler, sometimes with silvery sheen; hairs grey, brown at tip. Fore- and hindlimbs sparsely haired with short dark hairs. Tail relatively very long (ca. 100% of HB), dark brown to black, with numerous small dark bristles. Skull small and delicate; slightly domed. First upper incisor small, not hooked. First unicuspid large; second to fourth unicuspid smaller and subequal. M³ large. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Sylvisorex johnstoni. Dorsal pelage pale brown. Tail much shorter (T: 25–36 mm) and relatively shorter (ca. 50–60% of HB), with very short, barely visible hairs. Skull shorter (CI: 14.4–14.9 mm).

Distribution Endemic to Africa. Recorded only from W Cameroon (Mt Oku, L. Manengouba) and SE Nigeria (Gotel Mts).

Habitat Specimens from Mt Gangirwal in the Gotel Mts, Nigeria, were found in farm and grassland habitats (labels, ZFMK). Montane forests in Cameroon (Hutterer 2005b).

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.

Rainer Hutterer

Sylvisorex camerunensis

Sylvisorex granti GRANT'S FOREST SHREW

Fr. Musaraigne sylvestre de Grant; Ger. Grants Waldmoschusspitzmaus

Sylvisorex granti Thomas, 1907. Ann. Mag. Nat. Hist., ser. 7, 19: 118. Mubuku Valley, Rwenzori East, Uganda. 10,000 ft (3048 m).

Taxonomy Considered on morphological grounds to be the most archaic species of the genus (Heim de Balsac & Lamotte 1957). The form *camerunensis* is now considered as a separate species (Hutterer *et al.* 1992b). Synonyms: *mundus*. Subspecies: none. Chromosome number: not known.

Description Very small shrew with tail similar in length to head and body. Pelage length on back varies: ca. 4 mm (Kivu, DR Congo; 1700 m), 7 mm (Mt Kilimanjaro; 3500 m) (F. Dieterlen unpubl.). Dorsal pelage blackish with brownish tinge. Ventral pelage greyish-brown, slightly paler than dorsal pelage. Ears dark grey, very finely haired. Eyes very small (0.7 mm diameter). Fore- and hindfeet brownish. Tail relatively very long (ca. 100% of HB), appearing naked, but bearing very short bristles. Skull with domed cranium and short muzzle. Lower incisors with two marked denticulations. Lower first premolar with two cusps. Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

Sylvisorex johnstoni. Dorsal pelage pale brown, ventral pelage orange and contrasting markedly with dorsal pelage. Tail shorter (T: 25–36 mm) and relatively shorter (ca. 50–60% of HB). Rainforest habitats; parapatric in E DR Congo and Uganda. Both figured in Hutterer & Verheyen (1985).

S. lunaris. Head and body larger and much heavier (HB: 70–93 mm; WT: 9–20 g). Tail relatively shorter (ca. 65% of HB); blackish-

brown, very finely haired without longer bristles. Sympatric in montane areas of Albertine Rift Valley.

S. vulcanorum. Head and body on average larger (HB: 49.6 [43–56] mm). Skull usually shorter (CI: 15.5–16.1 mm). Marginally parapatric with *S. granti* in Rwanda and Uganda. Both figured in Hutterer & Verheyen (1985).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from E DR Congo (west of L. Albert, W Rwenzori Mts, Virunga Volcanoes, west of L. Kivu, Idjwi I. in L. Kivu); Rwanda (Nyungwe Forest); Uganda (E Rwenzori Mts, Virunga Mts, Mt Elgon); Kenya (Mt Kenya, Mt Elgon, Cherangani Hills, Aberdare Ranges); and Tanzania (Mt Kilimanjaro). Altitudinal distribution: 1510 m (Idjwi I., L. Kivu) to 3800 m (Lac Marion, Rwenzori Mts) (Heim de Balsac 1968b). A record from Bwindi Impenetrable N. P. is uncertain and requires verification (J. Kerbis in litt.).

Habitat Swamps, montane forests and moist bushy vegetation at altitudes above 1500 m where montane forests are the dominant vegetation. In the mountains west of L. Kivu, 22 specimens (= 66% of shrews) were collected in swamps dominated by *Cyperus latifolius* and/or *Cladium mariscus* at 1700 m, 19 from swamps (*Cladium mariscus*) in cultivated land at 1700 m, and three from montane swamps (*Cyperus latifolius*) at 2100–2300 m. Eight were captured in non-swampy habitats: four in forests and four in moist bushy vegetation (Dieterlen & Heim de Balsac 1979).

Abundance May be very abundant in swampy habitats (see above).

Remarks In E DR Congo, half of the ♀♀ (6 of 12) collected during the wet season (Oct–Jan) were pregnant or lactating. In the dry season (Jun–Aug), only one (of two) ♀♀ was pregnant. Embryo number: 1.6 (1–2), $n = 5$.

Conservation IUCN Category: Least Concern.

Sylvisorex granti

Sylvisorex howelli HOWELL'S FOREST SHREW (ULUGURU FOREST SHREW)

Fr. Musaraigne sylvestre de Howell; Ger. Howells Waldmoschusspitzmaus

Sylvisorex howelli Jenkins, 1984. Bull. Brit. Mus. (Nat. Hist.), Zool. 47: 65. Morningside, Uluguru Mts, Tanzania.

Taxonomy Includes *usambarensis*, which was previously considered as a separate species (e.g. Hutterer 1986b). Two subspecies are currently recognized: *S. h. howelli* and *S. h. usambarensis* (Hutterer 1986b), and there is some evidence that they may be separate species (Ray & Hutterer 1995). Phylogenetic analysis showed that there is considerable molecular variation among each of the Eastern Arc Mountain populations (see below), suggesting that each population has been isolated for a long period of time (Stanley & Olson 2005). Synonyms: *usambarensis*. Subspecies: two. Chromosome number: not known.

Description Small shrew with long bristle-hairs on the basal one-half to two-thirds of the tail. Dorsal pelage dark chocolate-brown. Ventral pelage paler brown. Dorsal and ventral hairs steel-grey at base, with chocolate-brown or brown at tip. Delineation between dorsal and ventral pelage not striking, but most obvious where the limbs join the body. Forelimbs chocolate-brown on dorsal and ventral surfaces. Pads on soles of hindfeet very dark brown. Tail relatively long (ca. 70% of HB), subtly bicoloured (darker above than below) with short hairs along entire length interspersed with longer bristle hairs on basal two-thirds. Nipples: not known.

Geographic Variation Jenkins (1984) and Hutterer (1986b) recognize two subspecies:

S. h. howelli: Uluguru Mts, Tanzania (based on a larger and higher skull).

S. h. usambarensis: Usambara Mts, Tanzania (based on a smaller and flatter skull). Stanley & Olson (2005) analysed all six known populations (see below), but did not formally describe any new subspecies. They found that specimens from East Usambara had the shortest and most narrow skulls, and specimens from Nguru had the longest and widest skulls.

Similar Species No other species of *Sylvisorex* has been recorded from the Eastern Arc Mts of Tanzania.

Distribution Endemic to Africa. Afrotropical–Afroalpine BZ. Disjunct distribution on several Eastern Arc Mts in Tanzania above 900 m. Recorded from the East Usambara, West Usambara, Nguu, Ukaguru, Nguru and Uluguru Mts (Jenkins 1984, Hutterer 1986b, 1993, Stanley *et al.* 1998, Stanley & Olson 2005).

Habitat Montane and sub-montane forests above 900 m. Rarely found in disturbed or drier regions of forest.

Abundance In areas of occurrence, the most common shrew of its size. In 1992, in the West Usambara Mts, comprised 90% of the total sample of shrews ($n = 43$) and 34% of the total sample of all non-volant small mammals ($n = 116$) (W.T. Stanley, unpubl.).

Remarks Nocturnal. In the West Usambara Mts in Aug, one ♀ was pregnant ($n = 10$). Embryo number: 2 ($n = 1$; one in each uterine horn; crown–rump length 3 mm; W. T. Stanley, unpubl.).

Males more commonly captured than ♀♀ – ratio 22 : 14. Of 28 individuals examined, all were assessed (by toothwear) as adults.

Conservation IUCN Category: Endangered.

The geographic range is fragmented and the number of suitable habitats is declining.

Sylvisorex howelli

Sylvisorex isabellae ISABELLA FOREST SHREW (BIOKO FOREST SHREW)

Fr. Musaraigne sylvestre d'Isabella; Ger. Bioko-Waldmoschusspitzmaus

Sylvisorex isabellae Heim de Balsac, 1968. Bonn. Zool. Beitr. 19: 31. Pic Santa Isabel, Refugium, Fernando Po (= Bioko I.), Equatorial Guinea. 2000 m.

Taxonomy Originally described as a subspecies of *Sylvisorex morio* (Heim de Balsac 1968d) but now considered to represent a distinctly smaller species on Bioko I. (Hutterer 2005b). *Sylvisorex morio* now restricted to Mt Cameroon. Included in *S. morio* by Heim de Balsac & Meester (1977). Synonyms: none. Chromosome number: 2n = 36, FN = 50 (Bamenda highlands, Schlitter *et al.* 1999; see also below).

Description Very small to small dark shrew. Pelage soft and dense; hairs ca. 5 mm. Dorsal pelage dark reddish-brown; hairs dark grey, brown at tip. Ventral pelage reddish-brown, usually slightly paler than dorsal pelage (depending on angle of view) with shot-silk appearance; hairs grey on basal two-thirds, pale brown on terminal third. Head similar in colour to dorsal pelage. Fore- and hindfeet brown, with inconspicuous dark brown scales and sparse short dark brown hairs; claws sharp. Tail relatively very long (ca. 90% of HB), blackish-brown, not bicoloured but slightly paler below. Braincase high-domed. First incisor long and hooked. First unicuspid large; second to fourth unicuspid smaller and subequal. Third molar medium. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Sylvisorex johnstoni. Dorsal pelage on Bioko I. rufous-brown. Smaller (HB: 45–53 mm; CI: 14.4–14.9 mm). Bioko I. and the mainland.

Distribution Endemic to Africa. Rainforest BZ/Afromontane–

Afroalpine BZ. Recorded only from Bioko I. (Equatorial Guinea). A similar species (referred to as this species by Schlitter *et al.* 1999) occurs in the Bamenda Highlands, Cameroon, but its status at present is uncertain (Hutterer 2005b).

Sylvisorex isabellae

Habitat Montane forest and grassland from 2000 to 2400 m (Heim de Balsac 1968d).

Abundance Uncertain. Probably rare and with a restricted distribution.

Remarks Sympatric with *Myosorex eisentrauti*, also endemic to 'Pic Santa Isabel' and 'Refugium' on Bioko I.

Conservation IUCN Category: Endangered.

Measurements

Sylvisorex johnstoni JOHNSTON'S FOREST SHREW (PYGMY FOREST SHREW)

Fr. Musaraigne sylvestre de Johnston; Ger. Johnstons-Waldmoschusspitzmaus

Sylvisorex johnstoni (Dobson, 1888). Proc. Zool. Soc. Lond. 1887: 577 [1888]. Rio del Rey, Cameroon.

Taxonomy Originally described in the genus *Myosorex*. Populations in S Gabon and W Congo exhibit considerable genetic distances, suggesting that cryptic species may be involved (Quéroutil *et al.* 2003). Synonyms: none. Chromosome number: 2n = 30, FN = 38 (Schlitter *et al.* 1999); one of the lowest diploid numbers of any species of African shrew.

Description Minute to very small shrew. Dorsal pelage pale brown (see also below). Ventral pelage orange, contrasting markedly with dorsal pelage. Short rostrum. Ears moderate, covered with short hairs. Tail of relative medium length (ca. 50–60% of HB), dark above and below with very short, barely visible hairs. Nipples: not known.

Geographic Variation Specimens from Bioko I. have rufous-brown dorsal pelage, and paler ventral pelage (BMNH).

Similar Species

Sylvisorex camerunensis. Dorsal pelage dark brown. Tail much longer (T: 55–61 mm) and relatively longer (ca. 100% of HB), dark brown to black, with numerous small dark bristles. Skull longer (CI: 17.0–18.1 mm).

S. granti. Dorsal pelage blackish with brownish tinge, ventral pelage slightly paler than dorsal pelage and not contrasting with it. Tail longer (T: 47–63 mm) and relatively longer (ca. 100% of HB). Montane habitats; parapatric in E DR Congo and Uganda. Both figured in Hutterer & Verheyen (1985).

S. isabellae. Dorsal pelage dark reddish-brown. Larger (HB: 54–63 mm; CI: 18.3–18.8 mm). Only known on Bioko I.

S. konganensis. Dorsal pelage brownish-grey. Tail pale brownish-grey, covered with short bristles, with a few longer bristles (1–3 mm) on basal 50%. Probably larger (HB: 64 mm; CI: 16.9 mm, n = 1). Sympatric only in SW Central African Republic and perhaps in N Congo.

S. lunaris. Dorsal pelage moderately dark greyish-brown to mid-brown; ventral pelage paler, not contrasting markedly with dorsal pelage. Much larger (HB: 70–93 mm; T: 45–56 mm; CI: 22.2–

22.9 mm). Parapatric in region of N Albertine Rift Valley.

S. morio. Much larger (HB: 61–71 mm; T: 50–59 mm; CI: 19.4–19.9 mm). Montane forest at 1000 m and above; recorded only from Mt Cameroon; possibly parapatric in Mt Cameroon area.

S. ollula. Much larger (HB: 91–110 mm; T: 59–71 mm). Sympatric throughout most of geographic range.

S. vulcanorum. Dorsal pelage dark sepia-brown to blackish-brown; ventral pelage slightly greyer. Tail much longer (T: 47–51 mm) and relatively longer (ca. 100% of HB). Skull longer (CI: 15.5–16.1 mm). Parapatric in region of N Albertine Rift Valley. Both figured in Hutterer & Verheyen (1985).

Distribution Endemic to Africa. Rainforest BZ (West Central Region, mainly in Gabon sub-region), and Eastern Rainforest–Savanna Mosaic. Recorded from two areas: (a) SW Cameroon, Gabon, Congo, and Central African Republic; and (b) E DR Congo, Uganda, Burundi and NW Tanzania. Also recorded from Bioko I.

Habitat Disturbed and undisturbed rainforest habitats (Hutterer & Schlitter 1996, J. C. Ray unpubl.); favours micro-habitats with relatively dense understorey (J. C. Ray unpubl.). In Gabon, occurs in rainforest and, to a lesser extent, marshy forest and riparian forest (Nicolas *et al.* 2004).

Abundance Consistently a common species in many central African shrew communities, representing (where found) 13–60% of shrews captured. Comprised 14% in Ngotto Forest, Central African Republic (n = 81; 11 spp.; Morvan *et al.* 1999), 15% in Belinga-Makokou, Gabon (n = 160; 11 spp.; Brosset 1988), 29% in Korup, Cameroon (n = 24, 9 spp.; Hutterer & Schlitter 1996), 31% at Mt Alen, Equatorial Guinea (n = 26; 8 spp.; Lasso *et al.* 1996), 35% at Mt Doudou, Gabon (n = 79; 9 spp.; Goodman & Hutterer 2004), 45% at Mt Doudou, Gabon (n = 693, 10 spp.; Nicolas *et al.* 2005) and 60% in Dzanga-Sangha, Central African Republic (J. C. Ray unpubl.). In all localities given above, it was the commonest species, except for Ngotto and Belinga-Makokou, where it was the second commonest species.

Remarks At Mt Doudou, Gabon, reproductive activity occurred throughout the year (Nicolas *et al.* 2003). Mean embryo number: 2 (n = 3) at Belinga-Makokou, Gabon (Brosset 1988) and 1.4 (n = 15) at Mt Doudou, Gabon (Nicolas *et al.* 2004). Most abundant species of shrew species found in small carnivore scats (frequency of occurrence: 36.7% of 311 scats) collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995, Ray 1998).

Conservation IUCN Category: Least Concern.

Sylvisorex konganensis KONGANA FOREST SHREW

Fr. Musaraigne sylvestre de Kongana; Ger. Kongana-Waldmoschusspitzmaus

Sylvisorex konganensis Ray and Hutterer, 1996. Ecotropica 1: 93. Kongana, Dzanga-Sangha Forest Reserve, Central African Republic.

Taxonomy Comparison of 16s rRNA sequences shows a close relationship to *S. ollula* (Quérrouil *et al.* 2001). Synonyms: none. Chromosome number: not known.

Description Small shrew. Dorsal pelage brownish-grey. Ventral pelage, tail, limbs and outer ear slightly paler in colour than dorsal pelage. Snout covered by numerous facial vibrissae. Ear small, rounded, paler than dorsal pelage, and covered by short hairs. Fore- and hindfeet pale, with relatively elongated digits; Digit 1 of hindfoot unusually long; tubercles absent from the inner surface of the sole. Tail of medium relative length (ca. 56% of HB), pale brownish-grey, covered with short bristles, with a few longer bristles (1–3 mm) on basal 50%. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Sylvisorex johnstoni. Dorsal pelage pale brown or rufous-brown. Tail dark above and below with very short, barely visible hairs. Smaller (HB: 45–53 mm; CI: 14.4–14.9 mm). Sympatric only in SW Central African Republic and perhaps in N Congo.

S. pluvialis. Tail and hindfoot longer (T: 67 mm; HF: 14 mm, n = 1). Tail relatively longer (ca. 90% of HB). Ventral pelage whitish-grey with white-tipped hairs. Possibly sympatric in SW Central African Republic and N Congo.

Sylvisorex konganensis

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Gabon sub-region]). Recorded only from SW Central African Republic (Ray & Hutterer 1995; Barrière & Nicolas 2000). Likely to occur also in N Congo.

Habitat One specimen collected in unlogged mixed forest with relatively open understorey (Ray & Hutterer 1995).

Remarks Probably very rare. Found in only 1.3% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995); comprised 0.8% of 1350 shrews captured in Ngotto Forest, Central African Republic (Barrière & Nicolas 2000).

Conservation IUCN Category: Data Deficient.

Sylvisorex lunaris MOON FOREST SHREW

Fr. Musaraigne sylvestre des Monts de la Lune; Ger. Mond-Waldmoschusspitzmaus

Sylvisorex lunaris Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 139. Mubuku Valley, Rwenzori East, Uganda. 12,000 ft (3810 m).

Taxonomy Synonyms: *ruandae*. Subspecies: none. Chromosome number: 2n = 58, FN = 80 (Maddalena & Ruedi 1994).

Description Small-medium to medium dark shrew. Pelage soft and dense with silky sheen; hairs ca. 4 mm. Dorsal pelage moderately dark greyish-brown to mid-brown; hairs dark grey on basal three-quarters, dark brown on terminal quarter. Head colour similar. Ventral pelage brownish-grey, paler than dorsal pelage (depending on angle of view) with shot-silk appearance; hairs grey on basal two-thirds, pale brown or beige on terminal third. Fore- and hindfeet dark brown with dark brown hairs; claws fairly long, sharp. Tail blackish-brown, relatively long (ca. 65% of HB); not bicoloured. First incisor moderately long and hooked. Third molar medium. Braincase high-domed. Nipples: 6.

Geographic Variation None recorded.

Similar Species

Sylvisorex granti. Head and body smaller and much lighter (HB: 45–65 mm; WT: 3–6 g). Tail relatively longer (ca. 100% of HB); appearing naked but bearing very short bristles. Sympatric in montane areas of Albertine Rift Valley.

S. johnstoni. Dorsal pelage pale brown; ventral pelage orange, contrasting markedly with dorsal pelage. Much smaller (HB: 45–53 mm; T: 25–36 mm; CI: 14.4–14.9 mm). Parapatric in region of N Albertine Rift Valley.

S. vulcanorum. Head and body much smaller and much lighter (HB: 43–56 mm, n = 5; WT: 3.5 g, n = 2). Skull shorter (CI: 15.5–16.1 mm). Dorsal pelage dark sepia-brown to blackish-brown. Sympatric in montane areas of Albertine Rift Valley.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded from Uganda (Rwenzori Mts), E DR Congo (mountains west of L. Kivu), Rwanda (Virunga Mts) and Burundi (mountains east of L.

Kivu). Also recorded on Idjwi I. (1500 m) in L. Kivu (Heim de Balsac 1968b). Altitudinal range: 1500–4100 m.

Habitat Very varied. In the Kivu district of E DR Congo, commonest in swamp and secondary bush (27 specimens) but also found in grass-bush (7), elephant-grass (6), and gallery woodland at 1600–1900 m; also recorded in secondary forest (3), bamboo (1) and montane swamp (1) at 1900–3300 m (Dieterlen & Heim de Balsac 1979). At higher altitudes in Rwenzori Mts, found in *Lobelia–Senecio* vegetation (J. Verschuren in Dieterlen & Heim de Balsac 1979).

Sylvisorex lunaris

Abundance Uncommon to common. In E Kivu, comprised 10% (6 of 56; 4 spp.) in elephant-grass, 17% (7 of 41; 6 spp.) in grassbush, and 32% (27 of 83; 8 spp.) in swamp and secondary bush habitats. At higher altitudes, the species is less common, comprising 0% (0 of 81; 8 spp.) in primary montane forest, 7% (2 of 28; 7 spp.) in mixed primary and secondary montane forest, 5% (1 of 20; 7 spp.) in bamboo and 1–2% (1 of 76; 6 spp.) in montane swamp habitats (Dieterlen & Heim de Balsac 1979).

Remarks Pregnancies recorded in Feb (1 of 1), Mar (2 of 5), Jun (1 of 2) and Jul (1 of 1); no pregnancies recorded in Jan (0 of 3) and Aug (0 of 6); no data for other months. Embryo number: 2.6 (2 [n = 2] to 4 [n = 1]) (Dieterlen & Heim de Balsac 1979).

Conservation IUCN Category: Vulnerable.

Sylvisorex morio MOUNT CAMEROON FOREST SHREW

Fr. Musaraigne sylvestre du Mont Cameroun; Ger. Kamerunberg-Waldmoschusspitzmaus

Sylvisorex morio (Gray, 1862). Proc. Zool. Soc. Lond. 1862: 180. Cameroon Mountain, Cameroon.

Taxonomy The form *isabella* from Bioko I., originally described as a subspecies of *S. morio* by Heim de Balsac (1968d), is now considered to be a separate species (Hutterer 2005b; see *S. isabella*). Synonyms: none. Chromosome number: 2n = 38 (Schlitter *et al.* 1999).

Description Small dark shrew. Pelage soft and dense; dorsal hairs 6 mm. Dorsal pelage dark russet-brown to black without conspicuous silky sheen; hairs dark grey with dark brown on tip. Ventral pelage slightly or moderately paler (depending on angle of view) with silky sheen; hairs grey with medium brown or pale brown tip. Ears short, partly concealed by pelage. Fore- and hindfeet brown, with short brown hairs. Tail relatively long (ca. 75% of HB), thin, blackish-brown, without long hairs. Skull slender in dorsal view with a semi-hexagonal braincase. Lateral view of dorsal profile flat from nasal to frontal. Braincase slightly domed. Upper toothrows gradually tapering inwards from M² to I¹ in ventral view. I¹ moderately long and hooked. M³ wide. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Sylvisorex johnstoni. Much smaller (HB: 45–53 mm; T: 25–36 mm; CI: 14.4–14.9 mm). Rainforest; possibly parapatric in Mt Cameroon area.

S. ollula. Much larger (HB: 91–110 mm); tail almost always longer (T: 59–71 mm) and relatively longer (ca. 57% of HB). Lowland rainforest; possibly parapatric in S Cameroon.

S. pluvialis. Dorsal pelage paler (greyish-brown). Tail relatively a little longer (ca. 90% of HB), with short dark hairs and a few longer bristles on basal 40%. In S Cameroon, recorded only from Korup N. P.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Mt Cameroon, Cameroon.

Habitat Montane forest at 1000 m and up to the limit of forest

at ca. 2100 m (Eisentraut 1973a, Heim de Balsac 1968d). One specimen in alpine grass and bushland at 3000 m (Eisentraut 1973a).

Abundance Probably fairly common although distribution is restricted. Heim de Balsac (1968b) commented that ‘à 1850 m (Musake-Hütte), l’animal est très commun ... et Eisentraut en capture de bonnes séries à chacun de ses voyages’ and also (Heim de Balsac 1958) that this species ‘parut ... le plus abondant des Soricidé du biotope’.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Key References Eisentraut 1973a; Heim de Balsac 1968d.**D. C. D. Happold & Rainer Hutterer***Sylvisorex ollula* GREATER FOREST SHREW

Fr. Musaraigne sylvestre d'Ollula; Ger. Große Waldmoschusspitzmaus

Sylvisorex ollula Thomas, 1913. Ann. Mag. Nat. Hist., ser. 8, 11: 321. Dja R., Bitye, Cameroon. 2000 ft (610 m).

Taxonomy Phylogenetic studies showed little difference between populations from W Congo and SW Cameroon (Quérrouil *et al.* 2003). Synonyms: none. Chromosome number: 2n = 38, FN = 64 (Schlitter *et al.* 1999).

Description Very large dark shrew, the largest species in the genus. Pelage dense and velvety with silky sheen; hairs 4–5 mm. Dorsal pelage medium to dark brown, or blackish, with slight russet tinge; hairs dark grey on basal two-thirds, dark greyish-brown to russet-brown on terminal third. Ventral pelage greyish-brown to medium brown, paler than dorsal pelage; hairs grey on basal two-thirds, greyish-brown on terminal third. Ears partly concealed by pelage. Fore- and hindfeet dark brown, sparsely covered by dark brown hairs. Tail of relative medium length (ca. 57% of HB), thin, blackish-brown, mostly naked with some bristles on basal 10%. Skull flat with braincase slightly domed. First upper incisor long and hooked. Third upper molar narrow. Sagittal and occipital crests on braincase well developed. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Sylvisorex johnstoni. Much smaller (HB: 45–53 mm; T: 25–36 mm).

Sympatric throughout most of geographic range.

S. konganensis. Dorsal pelage brownish-grey. Smaller and much lighter (HB: 64 mm; WT: 3 g, n = 1). Tail shorter (T: 36 mm, n = 1).

Possibly sympatric in SW Central African Republic and N Congo.

S. morio. Much smaller (HB: 61–71 mm); tail almost always shorter (T: 50–59 mm) and relatively shorter (ca. 75% of HB). Montane forest above 1000 m; Mt Cameroon only; possibly parapatric in S Cameroon.

S. pluvialis. Smaller (HB: 74 mm, n = 1). Tail relatively longer (ca. 90% of HB); ventral pelage whitish-grey with white-tipped hairs. Sympatric in Korup N. P., SW Cameroon and possibly in SW Central African Republic.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Gabon sub-region]). Recorded from S Cameroon, E Nigeria (Gotel Mts, 1900 m, adjacent to Cameroon border [Hutterer *et al.* 1992b]), Equatorial Guinea (Rio Muni), Gabon and SE Central African Republic. May also occur in W Congo. One record from SE DR Congo. One of the most widespread species of shrews within its principal geographic range (see Goodman *et al.* 2001).

Habitat Lowland rainforest. In Ngotto Forest, Central African Republic, abundant in dense unlogged forest characterized by a high frequency of natural disturbances (Morvan *et al.* 1999). In Minkébé Forest, Gabon, found only in marshland and homogeneous forest (Goodman *et al.* 2001).

Abundance Rare to common, depending on the locality. Comprised 0.5–33% of captured shrews, and sometimes one of the commonest of species, e.g. 5% (8 of 160; 11 spp.) at Belinga-Makokou, Gabon (Brosset 1988); 4% (1 of 24; = sixth of 9 spp.) at Korup N. P., Cameroon (Hutterer & Schlitter 1996); 10% (49 of 503; fourth of 9 spp.) at Mt Doudou, Gabon (Nicolas *et al.* 2004); 10% (8 of 79; = fourth of 9 spp.) at Mt Doudou (Goodman & Hutterer 2004); 11% (3 of 26; fourth of 8 spp.) at Mt Alen National Park, Equatorial Guinea (Lasso *et al.* 1996); 31% (25 of 81; first of 11 spp.) at Ngotto Forest, Central African Republic (Morvan *et al.* 1999); and 33% (4 of 12; = first of 7 spp.) in marshland at Minkébé Forest, Gabon (Goodman *et al.* 2001).

*Sylvisorex ollula*

Remarks Despite the commonness of this species, little has been recorded about its biology. Mean litter size: 2, $n = 2$; Belinga-Makokou, Gabon (Brosset 1988). Mean embryo number: 3.5, $n = 4$; Mt Doudou, Gabon (Nicolas *et al.* 2004). Found in 3.5% of 311 small carnivore scats collected in Dzanga-Sangha, Central African Republic (Ray & Hutterer 1995; Ray 1998). Ebola virus RNA detected in extracts of organs of one individual collected from Ngotto Forest, Central African Republic (Morvan *et al.* 1999).

Conservation IUCN Category: Least Concern.

Sylvisorex oriundus LESSER FOREST SHREW

Fr. Musaraigne sylvestre naine; Ger. Kleine Waldmoschusspitzmaus

Sylvisorex oriundus Hollister, 1916. Bull. Amer. Mus Nat. Hist. 35: 672. Medje, DR Congo.

Taxonomy Often included in *C. ollula* but regarded as distinct by Dieterlen & Heim de Balsac (1979). Synonyms: none. Chromosome number: not known.

Description Small dark shrew, with relatively long hindfoot. Dorsal pelage dark olive-brown to dark sepia-brown; hairs dark grey, olive-brown at tip. Flanks and ventral pelage dark greyish-brown, paler than dorsal pelage. Paler colouration on throat. Fore- and hindfeet pale buffy-brown; ankles blackish. Hindfoot relatively long (ca. 26% of HB). Tail relatively very long (ca. 91% of HB), dark above (darker than dorsal pelage), pale brown (on basal two-thirds) below. Upper first incisor hooked. Unicuspid form a graded series in size: first slightly larger than second, etc. (Description after Hollister 1916.) Nipples: not known.

Geographic Variation None recorded.

Similar Species No other species of *Sylvisorex* has been recorded from NE DR Congo.

Distribution Endemic to Africa. Rainforest BZ (East Central Region) and/or Northern Rainforest–Savanna Mosaic. Recorded only from NE DR Congo.

Habitat No information; presumably rainforest or rainforest–savanna mosaic.

Abundance Uncertain; known only by the holotype.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient; previously assessed as Vulnerable.

Sylvisorex oriundus

Sylvisorex pluvialis RAINFOREST SHREW

Fr. Musaraigne sylvestre de forêt pluvieux; Ger. Korup-Waldmoschusspitzmaus

Sylvisorex pluvialis Hutterer and Schlitter, 1996. In: Contributions in Mammalogy: A Memorial Volume Honoring Dr. J. Knox Jones, Jr. p.: 61. Ikenge Research Station (05° 16' N, 09° 08' E), Korup N. P., SW Province, Cameroon. 160 m.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Small-medium shrew similar to *Suncus megalura*. Pelage soft; hairs 3.6 mm dorsally, 3 mm ventrally. Dorsal pelage greyish-brown, paler than in other species of the genus. Ventral pelage whitish-grey with white-tipped hairs, a feature shared with *Suncus megalura* and unlike that of other species of *Sylvisorex*. Ears small, rounded, covered with short hairs. Fore- and hindfeet paler in colour than body; with slightly elongated digits. Tail relatively very long (ca. 90% of HB), with short dark hairs and a few longer bristles. Skull flat. First upper incisor small. Third upper incisor large (as in *Suncus megalura* and *Sylvisorex morio*). (Description from Hutterer & Schlitter 1996.) Nipples: not known.

Geographic Variation None recorded.

Similar Species

- Sylvisorex johnstoni*. Much smaller (HB: 45–53 mm; T: 25–36 mm, 50–60% of HB). Ventral pelage orange, hairs not white-tipped. Sympatric in Korup N. P., SW Cameroon; possibly sympatric in SW Central African Republic.
- S. konganensis*. Tail and hindfoot shorter (T: 36 mm; HF: 11.3 mm, n = 1). Tail relatively shorter (ca. 56% of HB). Possibly sympatric in SW Central African Republic and N Congo.
- S. morio*. Dorsal pelage darker (dark russet-brown to black). Tail relatively a little shorter (ca. 75% of HB), without long hairs. In S Cameroon, recorded only from Mt Cameroon.
- S. ollula*. Larger (HB: 91–110 mm). Tail relatively shorter (ca. 57% of HB); ventral pelage brown. Sympatric in Korup N. P., SW Cameroon and possibly in SW Central African Republic.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Eastern Nigeria and Gabon sub-regions]). Recorded only from the type locality, and from Kongana, Central African Republic (Ray & Hutterer 1995).

Habitat Rainforest.

Abundance Uncertain. Known only from the holotype in Cameroon and from carnivore scats in Central African Republic.

Remarks In Korup N. P., only one specimen was recorded amongst 24 shrews of nine spp. (three other species also represented only by a single specimen) (Hutterer & Schlitter 1996). Recorded from carnivore scats at Kongana, Central African Republic (Hutterer

Sylvisorex pluvialis

2005b). Ray & Hutterer (1995) refer to this species as *Sylvisorex* sp. A, and record that a single specimen of *Sylvisorex* sp. A was obtained among remains of 145 shrews (16 spp.).

Conservation IUCN Category: Data Deficient.

***Sylvisorex vulcanorum* VOLCANO FOREST SHREW (VOLCANO SHREW)**

Fr. Musaraigne sylvestre des volcans; Ger. Vulkan-Zwergspitzmaus

Sylvisorex vulcanorum Hutterer and Verheyen, 1985. Karisoke, Parc National des Volcans, Rwanda. 3100 m.**Taxonomy** Synonyms: none. Chromosome number: not known.

Description Minute to very small dark shrew (smallest in the genus) with relatively long tail. Pelage soft and fine; dorsal hairs 3–4 mm. Dorsal pelage dark sepia-brown to blackish-brown; hairs grey, sepia-brown at tip. Ventral pelage similar to dorsal pelage but slightly greyer; some hairs with white tips. Head similar colour to dorsal pelage. Ears small, slightly concealed by pelage. Fore- and hindlimbs darkly pigmented, covered by small dark brown hairs. Tail relatively very long (ca. 100% of HB), dark with many small black bristles. Braincase slightly domed. First upper incisor short and slightly hooked. Third upper molar wide. Nipples: not known.

Geographic Variation None recorded.**Similar Species**

Sylvisorex granti. Head and body on average smaller (HB: 56.1 [45–65] mm). Skull usually longer (CI: 16.1–17.0 mm). Marginally parapatric with *S. vulcanorum* in Rwanda and Uganda. Both figured in Hutterer & Verheyen (1985).

S. johnstoni. Dorsal pelage pale brown; ventral pelage orange, contrasting markedly with dorsal pelage. Tail much shorter (T: 25–36 mm) and relatively shorter (ca. 50–60% of HB). Skull shorter (CI: 14.4–14.9 mm). Parapatric in region of N Albertine Rift Valley. Both figured in Hutterer & Verheyen (1985).

S. lunaris. Head and body much larger and much heavier (HB: 70–93 mm; WT: 9–20 g). Tail relatively shorter (ca. 65% of HB). Skull longer (CI: 22.2–22.9 mm). Dorsal pelage moderately dark greyish-brown to mid-brown. Sympatric in montane areas of Albertine Rift Valley.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Mountains flanking the Albertine Rift Valley in E DR Congo, SW Uganda, Rwanda and Burundi. Marginally parapatric with *S. granti* in Rwanda and Uganda.

Habitat Remnant montane forest at 1900–3100 m (Hutterer *et al.* 1987).

Abundance Uncertain.

Remarks The relatively long tail suggests that this species may be partly scansorial.

Bats are the only mammals that can fly (although there are gliding mammals in other orders) and approximately 20% of the mammals of Africa are bats. Worldwide, there are 1116 species, placed in 18 families and 202 genera, of which 42% are monotypic and 16% have only two species. About 221 species of bats live in Africa; three other species have been reported but they are probably either vagrants or erroneously reported. Furthermore, some of the species undoubtedly contain subspecies or cryptic forms that will eventually be recognized as distinct species, and some species are of dubious status. Indeed, since these profiles were submitted in 2006, one new species has been described and six subspecies have been restored to specific status (details in Appendix) with the consequent addition of three species to the number recorded from Africa: these are not profiled individually but are mentioned in profiles of closely related taxa.

Of the 221 species recognized when this profile was submitted, 28 are megabats traditionally considered to belong to the suborder Megachiroptera, and 193 are microbats traditionally considered to belong to the suborder Microchiroptera. Evidence from recent phylogenetic studies supports the monophyly of the Megachiroptera, but the Microchiroptera is not currently considered to be a monophyletic taxon (see below). Nevertheless, megabats and microbats are sufficiently different in their morphology and habits to justify retaining their names here, in non-taxonomical contexts, at least until the relationships between the families of bats are fully understood.

All megabats belong to one family, the Pteropodidae (Old World Fruit Bats). In Africa, the Old World Fruit Bats are usually referred to simply as fruit bats and therefore, in African contexts, the terms megabat and fruit bat are interchangeable. In the profiles below, the megabats are referred to as fruit bats. In contrast, there are 17 families of microbats, of which eight are represented in Africa and, in the profiles below, species in these families are referred to collectively as microbats (not insect-bats or insectivorous bats, which are commonly used alternatives in other literature). Megabats (which are not always larger than microbats) feed almost exclusively on fruit and/or flower products, and perceive their surroundings mainly

by sight. In contrast, most microbats feed on insects, and perceive their surroundings mainly by echolocation. All African microbats are insectivorous, although some species also eat other arthropods, and at least two species also eat small vertebrates (see Food and Foraging): there are no blood-sucking microbats in Africa. Elsewhere, although most of the microbats are insectivorous, some feed on fruit and/or flower products, some feed on small fish, some feed on blood, and some of the insectivorous species also eat nocturnally migrating birds or small terrestrial vertebrates.

Almost all bats are nocturnal, and some of the explanations for this are given by Speakman (1995). Because the vast majority of species can echolocate and fly (self-powered flight as opposed to gliding), they can feed at night on flying insects (a resource that no other mammal and very few birds can exploit efficiently) and they can roost in totally dark day-roosts. The advantages of these resources to bats have directed the evolution of their morphology, physiology, behaviour, life-histories and almost every other aspect of their biology. However, the origin and early evolution of bats is poorly understood, mainly because the fossil record is very poor. The conventional view is that both megabats and microbats evolved from a common ancestor, which possessed gliding membranes between the fingers, and between the legs and tail, as well as between the arms and legs as in other gliders. Lengthening of the fingers followed, with the result that fully evolved bats can fly as competently as flying birds. However, despite this evolution of arms and legs into wings, many species of bats are also able to scuttle over the ground and/or climb with considerable agility.

Form and structure

In both megabats and microbats, there are species of different size. The length of the forearm (FA) gives a fair indication of overall size. Here, bats are described as very small, small, medium-sized, large or very large on the basis of FA, where each increment is one-fifth of the total range found in African species. For megabats, the total range is 38–163 mm; for microbats the total range is 20–124 mm; therefore the size-categories for megabats are slightly different to those for microbats. In all profiles of bats, when two similar species are distinguished on the basis of the size of FA (or any other character), one is only said to be ‘larger’ or ‘smaller’ than the other if there is no overlap in the ranges of FA of each species. If there is overlap, but the means are different, it is stated that one is ‘larger on average’ than the other or ‘smaller on average’. In contrast, some authors (especially taxonomists) may use ‘larger’ or ‘smaller’ in both of the above contexts. Bats have dorsal and ventral pelage on the head and body, sometimes extending onto the flight-membranes. Mid-dorsal hairs of African bats range in length from 2 to 19 mm. Hairs may be unicoloured or banded with different colours (used diagnostically). Most bats are grey or brown: striking colours or colour patterns are uncommon and, in Africa, limited to some of the species that roost by day in open places where camouflage is valuable. Microbats

are colour-blind and are unlikely to use colour patterns in social behaviour.

Some species have two colour-phases, grey-brown and orange: it has been suggested that the pelage changes from grey or brown (after the yearly moult) to orange or bright russet as it is oxidized by fumes within the day-roost (Constantine 1958, Brosset 1968, Wolton *et al.* 1982). Pelage colour can be bleached by ammonia from bat guano and stained by urine or glandular secretions. In *Miniopterus minor*, older browner pelage is replaced by blacker pelage when the bats moult (McWilliam 1988c); variation in colour in relation to moulting deserves investigation in other species, especially when taxa are distinguished mainly by colour. The effect of environmental humidity on colour also needs further investigation; there is a tendency for forms to be darker in more humid habitats.

Heads of bats are more varied in form than the heads of mammals in other orders. Megabats have dog-like heads with simple muzzles, simple erect ears and very large eyes. In contrast, many microbats have extraordinary heads. Those that emit echolocation calls through the mouth have simple, unadorned muzzles, but those that emit the calls through the nostrils, have a bizarre fleshy outgrowth (noseleaf) on the muzzle, which modifies the emitted sound. Furthermore, the pinnae (external ears) of microbats range from small and simple, to large and extremely complex in shape and structure. The inner surface is often heavily ridged and, in some species, is also creased, so the ears can be folded compactly against the head to reduce loss of heat and water during rest or hibernation. This is achieved by closing valves in blood-vessels so the pinnae deflate; when the valves open, the pinnae inflate very rapidly. Ears that are very large are often connected by a fold of skin linking the inner margins, and have thick cartilaginous margins and bracing, all of which maintain the aerodynamic shape of the ears during flight. Ears of microbats usually have a tragus – a cartilaginous structure arising near the external opening of the ear on the outer side of the pinna. Its presence or absence, size and shape are diagnostic characters. Microbats usually also have an antitragus (lobe near the base of the outer margin of the pinna). Eyes of megabats are very large and are modified to increase visual acuity at night: there is a tapetum lucidum, which causes the eyes to shine red in a spotlight. Eyes of microbats are much smaller and may be minute and partly hidden by pelage or a noseleaf. Bodies of all bats tend to be dorso-ventrally flattened, and tapered from shoulders to hips. Most female bats have one pair of nipples located in the pectoral region: some Vespertilionid species (e.g. *Otonycteris hemprichii*) have two pairs. Bats in the families Rhinolophidae, Hipposideridae and Megadermatidae (and in the extralimital Craseonycteridae) have an additional pair of nipples in the pubic region just anterior to the vagina, which provide holdfasts for the young: these may have at least some lacteal function in many species (Simmons 1993).

Wings of bats vary in shape (see Wing Morphology and Flight). The wing skeleton has the same bones as the forelimbs of other mammals: humerus essentially the same; ulna reduced and fused to radius to form the forearm; wrist as in other mammals but less flexible because the radius does not rotate. The bones supporting the outer part of each wing (the hand-wing) are the same as in the human hand except that the metacarpals and phalanges of the fingers are greatly elongated. The thumb (= first finger) is short and has a claw. Megabats also have a claw at the end of the second finger. The wing-membranes and interfemoral membrane are stretched around

and between the skeletal framework, as in Figure 22. Although these flight-membranes are extremely thin and elastic, they are supplied with blood vessels, muscles and nerves. The hindlimbs are slender and elongated with long toes and with sharp curved claws from which a bat can hang when it is not flying. The hindlimbs are seldom weight-bearing except in some species that are adapted for cursorial locomotion as well as flight and, as an adaptation for flight, they are rotated so the knees point backwards instead of forwards. As a consequence of this, the first toe (or hallux) of a bat is the one on the outside whereas, in all other five-toed mammals, it is the fifth toe which is outermost. The tail is short, vestigial or absent in megabats, but medium to very long in most megabats. Most bats have an interfemoral membrane, which stretches between the hindlimbs and usually encloses the tail. The camber of the interfemoral membrane can be altered during flight by a bony or cartilaginous spur (calcar), which projects from each heel into the trailing edge of the membrane. Each family of bats can be distinguished by the relative length of the tail, and the shape of the interfemoral membrane and the extent to which it encloses the tail.

Skulls of bats vary from family to family and from species to species, depending mainly on (a) diet and how strong the teeth, jaws and jaw muscles must be, (b) the presence or absence of a noseleaf, which requires skeletal support, (c) the emission of vocalizations (ultrasonic or otherwise), which may require resonating chambers in the rostrum and (d) habits such as nectarivory (which may require long narrow muzzles) or roosting in narrow cracks (which may require flattened skulls or other modifications). The following characters of skulls (Figure 23) are widely used to distinguish bats:

Zygomatic arches (= *cheekbones*). Range from massive, broad, widely flared and bony, to frail, slender and cartilaginous.

Sagittal crest. This is the ridge of bone running lengthwise along the top of the braincase; it can be well developed, low or absent.

Lambdoid crest. This is a ridge of bone running transversely across the back of skull at the junction of the dorsal and posterior bones of braincase; it can be well developed, low or absent.

Occipital helmet. This is a backward-pointing projection formed when sagittal and lambdoid crests are well developed and united; it can be present or absent.

Supraorbital crest. This is a ridge of bone along the upper rim of the orbit (eye-socket); it can be present or absent.

Postorbital process. This is a bony projection arising from the upper rim of each orbit and projecting outwards and downwards around the posterior of the orbit: it can be present or absent, long, slender and conspicuous, or concealed as result of merging with the supraorbital ridge.

Premaxillae (sing. *premaxilla*). These are the pair of bones that carry the incisors. Each premaxilla is comprised of a nasal branch that forms one side of the anterior end of the rostrum, and a palatal branch that forms one side of the anterior end of the bony palate (roof of mouth). Either the nasal branches, or the palatal branches, or both branches,

Figure 22. External characters of bats commonly referred to in profiles. The illustrated bat is hypothetical: no family or species has this combination of characters.

may be present or absent, well developed or reduced, independent or fused with other bones.

Anterior palatal emargination. This is an emargination in the anterior of the bony palate associated with loss or reduction of the palatal branches of the premaxillae (see above). It can be closed (non-existent), shallow (barely reaching incisors), deep (reaching level of canines) or very deep (reaching level of premolars or beyond), narrow or wide, and can vary in shape (e.g. U-shaped, V-shaped, bulb-shaped) (Figure 24).

Basiscranial axis. This is the line of the ventral profile of the skull, viewed laterally; usually mentioned when the alignment of the cranial (braincase) region relative to the alignment of the region anterior to the braincase is significant.

Bats have milk-teeth, which erupt prior to birth or soon after: they are shaped to enable neonates to 'lock' themselves onto a

nipple to prevent falling from the mother. Adult bats typically have fully differentiated incisors, canines, premolars and molars. The number of each type of tooth, and the shapes, positions and relative sizes of the teeth, are of taxonomic importance. Teeth may be separated or in contact; within the toothrow (in alignment with other teeth) or displaced either labially (towards the lips) or lingually (towards the tongue); and they may be unicuspid, bicuspid or tricuspid depending on the number of points (cusps) on the crown. Molar teeth of megabats have ridges around the outside with a shallow trough in the middle. Molar teeth of microbats, if fully developed, have a W-shaped pattern of sharp ridges (= commissures) on the grinding surface (Figure 23). However, a molar may be reduced (with the concomitant loss or partial loss of one or two of the most posterior ridges) in which case the pattern usually becomes N-shaped, incomplete N-shaped or V-shaped (for details see Family Molossidae). The length of the maxillary toothrow in bats is $C-M^1$, $C-M^2$ or $C-M^3$ depending on which molar is the most posterior molar.

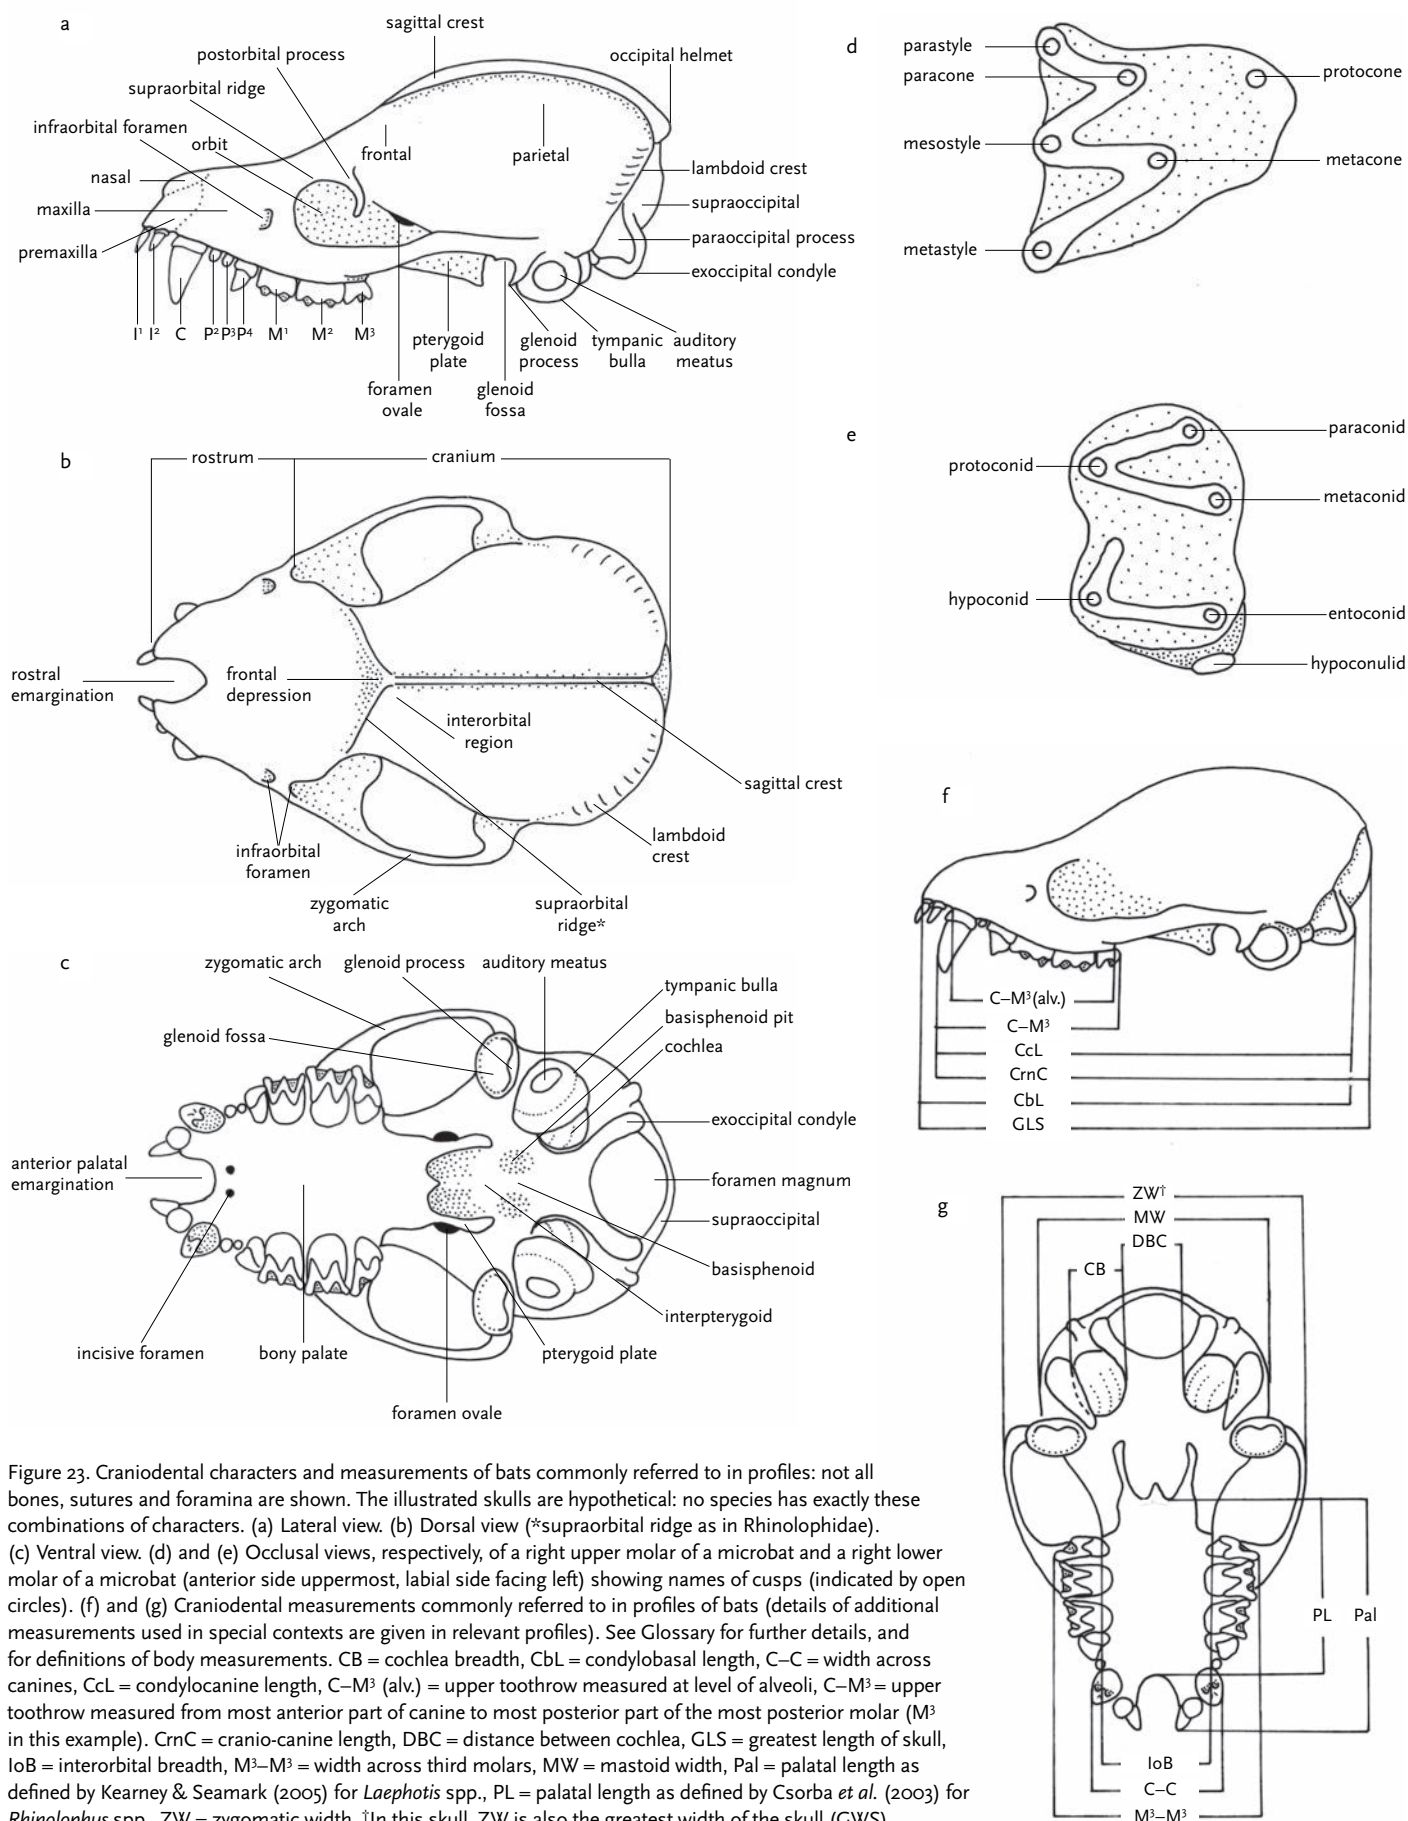

Figure 23. Craniodental characters and measurements of bats commonly referred to in profiles: not all bones, sutures and foramina are shown. The illustrated skulls are hypothetical: no species has exactly these combinations of characters. (a) Lateral view. (b) Dorsal view (*supraorbital ridge as in Rhinolophidae). (c) Ventral view. (d) and (e) Occlusal views, respectively, of a right upper molar of a microbat and a right lower molar of a microbat (anterior side uppermost, labial side facing left) showing names of cusps (indicated by open circles). (f) and (g) Craniodental measurements commonly referred to in profiles of bats (details of additional measurements used in special contexts are given in relevant profiles). See Glossary for further details, and for definitions of body measurements. CB = cochlea breadth, CbL = condylobasal length, C-C = width across canines, CcL = condylocanine length, C-M³ (alv.) = upper tooththrow measured at level of alveoli, C-M³ = upper tooththrow measured from most anterior part of canine to most posterior part of the most posterior molar (M³ in this example). CrnC = cranio-canine length, DBC = distance between cochlea, GLS = greatest length of skull, IoB = interorbital breadth, M³-M³ = width across third molars, MW = mastoid width, Pal = palatal length as defined by Kearney & Seamark (2005) for *Laephotis* spp., PL = palatal length as defined by Csorba *et al.* (2003) for *Rhinolophus* spp., ZW = zygomatic width. †In this skull, ZW is also the greatest width of the skull (GWS).

Figure 24. Shapes of the anterior palatal emargination in bats. (a) Closed (e.g. some *Tadarida pumila*); (b) shallow (perhaps does not occur in African bats); (c) deep and narrow (e.g. *Otomops martiensseni*); (d) very deep, wide and U-shaped (e.g. *Glauconycteris poensis*); (e) bulb-shaped (e.g. *Tadarida bivittata*); (f) V-shaped (e.g. *Taphozous perforatus*).

Figure 25. Outlines of flight membranes, bodies and ears of bats with aspect ratios ranging from very high to very low. In all examples except *Rhinopoma* and *Mimetillus*, the layout of the wings follows McKenzie & Rolfe (1986) and the outlines were traced from fresh specimens. (a) *Tadarida nigeriae* (Molossidae): aspect ratio very high. (b) *Tadarida pumila* (Molossidae): aspect ratio high. (c) *Taphozous mauritanus* (Emballonuridae): aspect ratio: medium. (d) *Rhinopoma hardwickii* (Rhinopomatidae): aspect ratio low. (e) *Rhinolophus blasii* (Rhinolophidae): aspect ratio low. (f) *Mimetillus moloneyi* (Vespertilionidae): aspect ratio low. (g) *Epomophorus labiatus* (Pteropodidae): aspect ratio very low. (h) *Nycteris hispida* (Nycteridae): aspect ratio very low.

Wing morphology and flight

Wings of bats differ in shape: there are marked differences between families (Figure 25) and less obvious differences between species belonging to the same genus. The area and shape of the wings in relation to the mass of the bat determine how fast and how slowly the bat can fly, how fast it must be travelling in order to fly, how rapidly and effectively it can turn and manoeuvre, and whether it can hover or take off from the ground. From family to family, these are highly variable. The parameters of greatest significance are aspect ratio (ratio of wing-length to wing-breadth), wing-loading (mass divided by wing-area) and tip-shape. Wingspans and wing-areas can be measured in several ways. Two methods in common usage are those of (a) Norberg & Rayner (1987) and (b) McKenzie & Rolfe (1986) (Figure 26). In method (a), the bat is laid out with the leading edges of its wings at right-angles to the mid-line of the body; wingspan is distance between the tips of each wing and wing-area is the combined area of the wings, interfemoral membrane and body. In (b), the wings are angled forward into a position that approximates the position of the wings when wing-loading is minimal during the downstroke; wingspan is more complex than simply the distance between the wing-tips, and the wing-area includes the area of the head and ears. Measurements obtained by these different methods are not the same. Furthermore, the numerical differences are not consistent because in (b) the wings are always evenly stretched irrespective of species, whereas in (a) the wings are almost evenly stretched in species with long narrow wings but very unevenly stretched in species with short broad wings (M. Happold unpubl.). Here, the problems associated with differences in method are avoided by using the following conventions in the species profiles:

Wingspan (WS). Given in 'Measurements' (with method in brackets), to give a rough indication of the bat's size.

- (a) Wings with leading edges at right-angles to mid-line of body: $WS = \text{distance from wing-tip to wing-tip}$ (Figure 26a; Norberg & Rayner 1987).
- (b) Wings angled forward with all flight-membranes fully and evenly stretched: $WS = \text{approximately the distance from wing-tip to wing-tip via centre of body}$ (Figure 26b; McKenzie & Rolfe 1986).
- (c) Wings forward as in (b) but $WS = \text{straight distance from wing-tip to wing-tip}$. An old method commonly recorded with museum specimens.
- (d) Method not known.

Aspect ratio. Calculated by dividing the square of the wingspan by the wing-area. Described as very low, low, medium, high or very high, where each increment is one-fifth of the total range found in African bats. Methods (a) and (b) for measuring wingspan and wing-area, yield similar (albeit not identical) results for aspect ratios, and the range for African bats is 4.8–10. Narrow wings have high aspect ratios.

Wing-loading = mass (kg) divided by wing-area (m^2). Described as very low, low, medium, high or very high, where each increment is one-fifth of the total range found in African bats. For wingspan method (a) the range for the African species for which reliable data

Figure 26. Calculating wingspan and 'wing area' using the methods of (a) Norberg & Rayner (1987) in which the leading edge of the wing is at right angles to the mid-line and (b) McKenzie & Rolfe (1986) in which only the humerus is at right angles to the mid-line. The illustrated species is *Nycteris thebaica* (HC 2942) that maximally demonstrates the different results of each method; the outlines were traced from one fresh specimen. A = point of attachment of wing to ankle, B = closest point on the leading edge of the wing to A, C = mid-point between A and B, D = wing-tip, E = point at which a line from C meets the mid-line at right angles. The areas used in each method of calculating aspect ratio are stippled. For method (a), wingspan = distance between wing-tips in straight line. For method (b), wingspan = $2(CD + CE)$.

are available is 4.5–20 Newton/ m^2 . Wing-loadings above this range are described as exceptionally high, but they need confirmation. For method (b), the range is 4–18 N/ m^2 . Bats with narrow wings have high wing-loadings unless the wings are also long.

Tip-shape. Refers to the length, area and pointedness of the hand-wing (between the fingers) relative to the arm-wing (between the body, hindlimb and fifth finger). Here we describe tip-shape very roughly as short or long, rounded or pointed (for further information see Norberg & Rayner 1987).

Some of the characteristics of a bat's flight and the parameters with which they are correlated are:

Speed. High speed is correlated with high wing-loading. Bats with high wing-loadings must travel at high speed to maintain flight. Flight speeds of at least 27 m/sec (9.72 km/h) (in a molossid) are known (Norberg & Rayner 1987). Here, flight speeds are described as very slow, slow, medium (= average) or fast, but the ranges of flight speeds for each of these categories have not been defined.

Turning. Bats initiate a turn by altering the form of their flight-membranes so one wing has more lift than the other and the bat rolls. The turn itself is then achieved by adjusting the wings, legs and/or interfemoral membrane so drag increases on the side of the dipped wing and the bat turns with the dipped wing on the inside of the turn. Radius of turn is proportional to speed. For this reason, some

bats swoop upwards to lose speed before rolling; some almost stall and therefore achieve 'stall-and-twist' turns, which are extremely tight and wonderfully acrobatic to watch. A 'banked' turn is one in which there is little change in height or speed.

Manoeuvrability is a measure of the minimum space required for a turn at a given speed. Because the radius of a turn increases with increased speed, manoeuvrability is favoured by slow flight and therefore low wing-loading. Manoeuvrability in confined spaces (i.e. in densely cluttered environments) is also favoured by short wings and small overall size. Small, lightweight bats with short broad wings, such as *Nycteris hispida*, can keep flying and manoeuvring very easily within a cubic metre of space. Large heavyweight bats with broad wings need more space because of their larger size.

Agility is the rate at which a turn can be initiated. It is favoured by fast flight and high wing-loading. Bats with great agility make high-speed swerves and swoops in pursuit of insects.

Energetic cost of flight is the energy used per unit time or per unit distance. It is lowest when aspect ratio is highest. Economical slow flight is favoured by long narrow wings; economical fast flight by short narrow wings.

Hovering is favoured by relatively long wings, low wing-loading, small overall size and rounded wing-tips. The wing-beat in hovering is very complex.

Losing height. Some bats, such as the European *Nyctalus noctula*, lose height by rolling through 180° and flying upside down; in this position, the lift-force on the wings is directed downward and this force, together with gravity, results in very rapid descent. Some bats, such as *Otomops martiensseni*, perform a series of side-slips (fish-tailing) to lose height (for details see Norberg 1976).

Landing. Some bats land directly on vertical surfaces, often after swooping upwards to lose speed, and they adjust their posture to head-down after landing. Others perform a half-roll while slowing to stalling speed, which enables them to grasp a perch with their hindfeet and hang freely from it.

Taking-off. Flight requires speed and the higher the wing-loading, the greater the speed that is required. Diving from a high site is the most economical way to accelerate to achieve the required speed and, for bats such as molossids with very high wing-loadings, the necessary speed cannot be achieved in any other way. For bats with low wing-loadings, it is possible to muster enough energy to beat the wings and achieve sufficient acceleration to reach the comparatively slow speeds required for flight, and these bats can take off from level surfaces such as the ground.

Load-carrying. Some bats carry extra heavy loads after feeding, during pregnancy and while carrying young, heavy prey or heavy loads of seasonally accumulated fat. Bats that habitually carry heavy loads have relatively large wings and low wing-loading. Small bats have greater reserves of power and can carry additional weight more easily than larger bats.

Long-distance flight. Long distances are flown by bats that are nomadic or migratory, those that fly long distances between roosts and feeding-grounds, and those that spend many hours flying to obtain flying insects. Economical flight is favoured by high aspect ratios, so these bats have narrow wings. Migratory bats do not necessarily have to fly fast, so many have rather low wing-loadings in conjunction with high aspect ratios. In contrast, bats such as molossids and some emballonurids which forage at high speeds for long periods have high aspect ratios in conjunction with high wing-loadings.

The flight characteristics of bats can be compared in many ways (e.g. Aldridge & Rautenbach 1987). A very simple way is to observe individuals in a 1 × 1 × 1 m enclosure (mosquito netting over a frame) and record whether or not they can fly across the enclosure, complete a full circuit, fly a figure-of-eight with banked turning, gain height, take off from the ground and land on the ceiling (M. Happold unpubl.). The maximum number of circuits flown per flight reflects how easily a bat can manoeuvre in this very confined space, and the minimum radius of banked turns can be determined from the complexity of the manoeuvres (e.g. a figure-8 with banked turns indicates minimum radius <25 cm). Bats that cannot turn around within one cubic metre can be tested in small rooms. The flight characteristics of 36 species of Malawian microbats (six families, 15 genera) were assessed in this way, and the maximum number of circuits/flight and other flight characteristics are given here (see profiles).

Foraging and food

Most megabats feed on soft ripe fruits of trees. For convenience, figs (which are really the flowers of fig trees – *Ficus* spp.) are included here in the category of soft fruits. Some megabats also eat the buds, flowers, pollen and/or nectar of other trees; some feed only on pollen and nectar, and some only on nectar. Megabats have excellent night-vision, colour-vision and a highly developed sense of smell. They detect food at great distance by smell, and at close range also by sight. Most megabats obtain fruit and/or flower products by landing on the vegetation and then feeding. Some carry fruit to a nearby perch before eating it. Some hover briefly before landing, but apparently no African megabats sustain hovering while feeding (cf. the frugivorous phyllostomid bats of the Americas) (Hill & Smith 1984). Some land to take fruit from the ground.

All African microbats are insectivorous but some species also eat other arthropods (e.g. *Nycteris thebaica*, *Otonycteris hemprichii*). *Nycteris grandis* also eats small terrestrial vertebrates and *Nyctalus lasiopterus* also eats nocturnally migrating birds. However, no African microbats are currently known to habitually eat fruit, flower products, fish or blood (as some microbats do elsewhere). There are no blood-sucking bats in Africa. Some species specialize on hard-shelled insects such as beetles, some on soft-bodied insects such as moths, and some are opportunistic feeders that take whatever comes provided the size is manageable. Diets often change between seasons and bats tend to be more opportunistic when insects are scarce.

Depending on their flying abilities and what they are able to perceive visually and by echolocation, microbats forage for different sorts of insects in different ways and places and thereby avoid excessive competition with other species. The methods of foraging exemplified

by African microbats, and the situations where each method takes place, are listed below with examples. Some bats use more than one method.

Fast-hawking. High above ground and vegetation, in very open spaces. Flying insects are detected at long range; pursued with high speed and great agility but poor manoeuvrability; eaten in flight. Foraging flights last several hours and cover long distances. (Emballonurids and molossids.)

Slow-hawking. Semi-open spaces below or close to canopies, small clearings and tunnels in vegetation, and closer to the ground than in fast-hawking. Flying insects are detected at short-range; pursued with moderate speed, moderate agility and moderate to great manoeuvrability; eaten in flight. Foraging flights shorter; interspersed with rest periods. (Most vespertilionids.)

Moderately fast-hawking. Intermediate between fast- and slow-hawking. Combines foraging at moderately high speed in open spaces fairly high above ground and vegetation, with foraging at slower speeds with great manoeuvrability in moderately cluttered spaces. (Some vespertilionids.)

Fly-catching. Close to vegetation and ground in moderately cluttered spaces. The bat hangs from a perch and waits until an approaching flying insect is detected at close range. The prey is pursued during a brief flight with considerable manoeuvrability, and taken to the perch before being eaten. In some literature, this behaviour is included in perch-hunting. (Some rhinolophids and hipposiderids.)

Gleaning. Very close to vegetation and/or the ground in densely cluttered spaces. Non-flying prey is taken from surfaces including foliage, tree-trunks, walls and ground. Hover-gleaners glean while hovering or flying slowly. Foliage-gleaners specialize in taking prey from foliage and tree-trunks and are usually hover-gleaners. Ground-gleaners often land to catch prey but may also take it while flying slowly. Gleaners, especially ground-gleaners, are often perch-hunters (see below). (Some nycterids, rhinolophids and hipposiderids, and a few vespertilionids.)

Perch-hunting. A general term referring to any foraging behaviour in which the bat hangs from a perch while searching for its prey and then returns to the perch to eat and/or to resume searching. Fly-catching is a type of perch-hunting. Ground-gleaning (and perhaps gleaning from other surfaces) is often combined with perch-hunting.

Trawling. Refers to the taking of insects (or small fish) from water surfaces. Prey is taken by the hindfeet: trawling bats have long toes and sharp claws, which act as grapnels. (*Myotis capaccinii*, *M. bocagii*.)

Chasing. Refers to the detection and pursuit of non-flying prey (e.g. cockroaches, resting moths) by bats that scuttle over horizontal and sloping surfaces, or the ground, in pursuit of the prey. (*Taphozous mauritanus*, *Tadarida condylura*, *T. pumila*.)

Foraging strategies are very complex. They are determined not only by 'capture' techniques but also by trade-offs between quantity of food versus its quality, duration of foraging and feeding versus

duration of other activities, and the advantages of obtaining food versus the risk of predation and/or aggression from competitors. African bats whose foraging strategies have been studied in detail (albeit not necessarily in Africa) include *Hypsignathus monstrosus*, *Hipposideros vittatus*, *Cardioderma cor*, *Lavia frons*, *Nycteris grandis*, *N. thebaica*, *Nyctalus leisleri*, *Myotis emarginatus*, *M. nattereri* and to a lesser extent *Epomophorus wahlbergi*, *Hipposideros caffer*, *Tadarida teniotis*, *Pipistrellus capensis*, *P. kuhlii* and *Scotophilus leucogaster*.

Echolocation

Microbats are not blind but, in most species, eyesight is poorly developed and they use vision mainly to tell when it is dark enough to begin foraging, and when moonlight is bright enough to increase danger from predators. Possibly, migrating microbats use vision to perceive landmarks, and some species use vision, at least to some extent, to locate and catch prey, and to detect the approach of predators. Also, in well-known environments, some rely considerably on memory to avoid obstacles (which is why they can be caught in mist-nets). However, microbats mainly perceive their surroundings and locate targets (prey) by using reflected ultrasonic sound instead of light to 'see' in the dark. This procedure is called echolocation, and it enables microbats to perceive range, movement, size, shape and texture with a degree of sophistication that is almost unimaginable to humans (Simmons *et al.* 1979, 1995, Pye 1980, Simmons & Stein 1980, Simmons & Grinnell 1988 and others). In contrast, eyesight is well developed in megabats, and echolocation probably occurs in only one genus, *Rousettus*. Species in this genus produce clicks with their tongues and use these to orientate in total darkness but, unlike the sophisticated echolocation calls made by microbats, these clicks are broad bandwidth, impulse sounds with no clearly defined wave structure, no evidence of frequency modulation, and amplitude patterns that are rapid and transient (Pye 1980). Echolocation calls of microbats are produced in the larynx, modified by the surrounding tissues and spaces, and emitted through the mouth or through the nostrils. Noseleaves, which surround the nostrils of some microbats, beam the sound in front of the bat. Some bats emit echolocation calls that are extremely loud (100–110 decibels at 10 cm distance from the bat); in contrast there are 'whispering' bats whose calls are very quiet (60 decibels at 10 cm). To prevent deafening by their own calls, bats block their hearing mechanism while each call is being produced. Echolocation calls are of very short duration (e.g. 0.2–84 ms in African species), and the dominant frequencies range from ca. 10–212 kHz in African bats. Humans can hear 3–18 kHz, so the echolocation calls of a few species of bats are audible to humans. Echolocation calls may be constant in frequency (CF), or the frequency may be modulated (FM) which means that the frequency increases or decreases evenly within a few microseconds. Many bats emit calls that have both CF and FM components.

Echolocation enables microbats to perceive acoustic images that correspond to the visual images perceived by animals with eyesight. Range (distance) of an object is perceived by the time taken for an echo to return and for this purpose short calls are better than long calls. Sizes of objects can be perceived with greater accuracy by using high-frequency calls (the higher the better) and this is the main reason why bats use ultrasonic calls. With a call of 50 kHz (which has a wavelength of 6.8 mm) objects as small as 6.8 mm can

be measured accurately. However, high-frequency sounds do not travel as far as lower-frequency sounds, so a bat that emits calls of 160 kHz, for example, can only detect prey that is closer than 30 cm and it must fly slowly to avoid collisions. In contrast, bats that emit lower-frequency sounds (e.g. 20 kHz) can detect prey at distances of up to 20 m and have no need to fly slowly. Echoes from stationary objects come back to a stationary bat with the same frequency as the emitted call and this informs the bat that the objects are stationary. In contrast, the frequency of an echo from an object that is moving towards the bat, or away from it, will be increased or decreased by the Doppler effect, and this enables bats to perceive the speed and direction of the moving object (Möhres 1953, Schnitzler 1968, Bell & Fenton 1984). If the bat is moving as well as the object, it can make allowance for Doppler shifts created by its own movement, and can still perceive how objects are moving in relation to itself. Long CF calls are best suited for perceiving Doppler shift and rhinolophids and hipposiderids emit these calls to detect 'flutter' – the fluctuating rise and fall in the frequency of an echo reflected from an object that is moving to and fro, such as the fluttering wing of a moth. Long CF calls are also good for detecting prey that is moving in front of a stationary background and, although they are not good for perceiving range, they are often emitted by bats that forage in cluttered environments. In contrast, short CF calls are good for detecting the presence and range of prey in open spaces, but provide little other information.

To distinguish a stationary moth from the bark of a tree, or a flying beetle from a flying moth, a bat needs to perceive size, shape and texture and for these purposes it needs to emit a broad range of frequencies simultaneously or as near to simultaneously as possible. This can be done by producing FM calls or by producing harmonics. Harmonics are produced by having anatomical structures around the larynx, mouth and nasal cavities that vibrate in sympathy with the vocal cords. The lowest frequency produced by the cords is the fundamental frequency or first harmonic. The second harmonic is twice the frequency of the fundamental; the third is three times the fundamental and so on. Many microbats place maximum sound energy in the second harmonic, but by producing up to four harmonics they greatly improve the discriminating qualities of the call.

Frequency modulated (FM) calls are 'steep' if the frequency changes rapidly with time, or 'shallow' if the frequency changes slowly. Harmonics may be present. The difference between the highest and lowest frequency of any harmonic is the bandwidth: bandwidths range from broad to narrow. FM calls can provide a bat with enough information about size, shape and texture to perceive a camouflaged moth on a tree-trunk, which would probably be overlooked by a bird in daylight. However, FM calls do not provide detailed information about the speed and direction of travel of a flying target. Bats compensate for this by emitting up to 200 calls per second, and comparing the echoes of consecutive calls. Call repetition-rate increases as a bat approaches a target and needs more accurate information. These rapidly emitted FM calls are referred to as feeding-buzzes.

Because CF and FM calls differ in what they enable a bat to perceive, and how effective they are in cluttered environments or open spaces, at close range or at long range, most bats produce multi-purpose calls that have both CF and FM components. They can also emphasize either the CF component or the FM component, or switch entirely from one type to the other, depending on what information they require at the time. Likewise, they can add or delete

the harmonics. Some bats are more versatile than others. Extreme versatility is shown by some vespertilionids and molossids (Figure 27). When searching for prey in open spaces, their search-phase calls are lower-frequency short CF or short shallow FM sweeps with only one harmonic: these narrow bandwidth calls are very appropriate for long-range target detection. As a bat approaches a target, it makes approach-phase calls in which a broad FM sweep is introduced at the beginning of the call: these calls are good for target detection and resolution of its size, shape and movement. As the bat comes even closer, the CF component shortens and disappears and the calls become short, rapidly repeated broad steep FM sweeps that provide superb resolution of target range. In sequence, such a bat might 'see' something at a distance that looks promising; as it comes closer it has a good 'look' to see if it is moth, beetle or some other suitable prey and then, having decided to catch it, it concentrates only on where exactly it is and what it might be doing to avoid capture. Some insects are able to 'hear' ultrasonic calls in the range 20–50 kHz, and respond to the sound of an approaching bat by closing their wings and falling out of the way (Fenton & Fullard 1981, Jacobs 2000).

Echolocation calls, habitat preferences, food, wing morphology and flying ability have evolved in unison and there are strong relationships between them (e.g. Fenton 1982, Norberg & Rayner 1987, Neuweiler 1989, Jones 1993, Schnitzler & Kalko 2001). Therefore it is not surprising that bats with different phylogenies and life-styles emit different echolocation calls. Bats belonging to different families have very different life-styles and they emit echolocation calls that are different and therefore characteristic of each family (see family profiles). If the calls are made audible to humans by a bat-detector, the calls of different families can be recognized by ear. It was once thought that bats emitted species-specific calls and that bats, like birds, could be recognized by their calls (e.g. Fenton & Bell 1981). While this is largely true, recent studies have shown that intra-specific variation is common and that it can be linked, for example, to the purpose of the call, to geographic distribution, to differences in the habitat or foraging areas being occupied at the time, and to the presence of conspecifics. Nevertheless, in particular areas, echolocation calls are a useful means of recognizing species and this has various ecological and behavioural applications, such as following activity patterns at particular localities. Differences in echolocation call characteristics have also enabled cryptic species to be recognized, e.g. the European *Pipistrellus pygmaeus* was discovered because its echolocation calls differ from those of *P. pipistrellus* (Jones & Van Parijs 1993).

Distinguishing the calls of different species by ear is rarely possible, but sonograms (graphs of frequency against time, Figure 28) and computer software that analyses data contained in recordings and sonograms, enable researchers to see and measure the most important physical characteristics of calls. Complete sonograms show all harmonics, but bat biologists often use sonograms that only show the harmonic with maximum energy (= dominant harmonic). Search-phase calls are more useful than approach-phase calls and feeding-buzzes as a means of distinguishing species, but different authors describe these calls in various ways using different characteristics and different terms. Here, search-phase calls are described using the following parameters and using the following terms, which have been derived from diverse sources, including Simmons & Stein (1980), Fenton & Bell (1981), Taylor (1999a), Schnitzler & Kalko (2001) and M. Happold (unpubl.):

Call-shape. The way frequency changes with time as shown on sonograms (spectrograms). Described by terms (or combinations of terms) such as CF, FM, linear, sigmoid, curvilinear, steep or shallow, angular or smooth, and Q (quasi = almost); e.g. the hockey-stick

shaped calls of some vespertilionids are described here as steep FM/QCF (where / marks the transition from the steep FM component to the 'heel', which is almost CF). For call-shapes of African species, and the terms used here to describe them, see Figure 28.

Figure 27. Sonograms of sequences of echolocation calls that have very diverse shapes (M. Happold unpubl.). (a) Calls emitted by a vespertilionid (*Scotoecus hirundo* from Malawi) while searching for prey (search-phase), approaching prey (approach-phase) and then catching it ('feeding buzz'). (b) One search-phase call followed by approach-phase calls associated with rapid acceleration, emitted by a molossid (*Tadarida pumila*); this sequence lacks a 'feeding buzz' indicating that the potential prey was not attacked and captured. Time axis marked at intervals of 10 ms.

Figure 28. Sonograms of echolocation call-shapes of African bats and the terminology used here to describe them. (a) CF. (b) Shallow linear FM. (c) Steep linear FM. (d) FM/CF/FM. (e) CF/FM. (f) Angular shallow/steep FM. (g) Shallow curvilinear. (h) Angular steep/shallow FM. (i) Smooth steep/shallow FM. (j) Steep FM/QCF. (k) Shallow sigmoid FM. (l) Steep sigmoid FM. All call-shapes, except (d) and (e), are traced from sonograms in which the frequency and time scales are the same: frequency axis marked at intervals of 10 kHz, time axis marked at intervals of 10 ms. For calls-shapes (d) and (e), each interval on the time axis corresponds to 50 ms. Abbreviations: CF = constant frequency, FM = frequency modulated, QCF = quasi (almost) constant frequency. Slashes indicate transitions between different components of a call.

Table 9. Resource partitioning within a community of microbats in miombo woodland in Liwonde N. P., Malawi (M. Happold & D. C. D. Happold pers. obs.). Diets are based mainly on data from Zambia and Zimbabwe. Insects that apparently form a major part of the diet are listed: for details see species profiles. Probably all microbats are opportunistic feeders to some extent, but the size of a bat and its dentition and jaw-strength impose limitations on what it can eat. For definitions of terms, see text.

| Family | Species | Size | Aspect ratio | Wing-loading N/m ² | Foraging | Level of clutter | |
|------------------|--|------------------|--------------|-------------------------------|--|------------------------|--|
| Molossidae | <i>Tadarida condylura</i> | Small | High | Very high | Fast-hawking | Very low | |
| Molossidae | <i>Tadarida pumila</i> | Very small | High | Medium | Fast-hawking | Very low | |
| Emballonuridae | <i>Taphozous mauritanus</i> | Medium | Medium | Medium | Fast-hawking | Very low | |
| Vespertilionidae | <i>Scotophilus dinganii</i> | Small | Medium | Medium | Moderately fast-hawking | Low–moderate | |
| Vespertilionidae | <i>Miniopterus fraterculus</i> | Small | High | Low | Fast- and slow-hawking | Low–moderate | |
| Vespertilionidae | <i>Scotophilus viridis</i> | Small | Low | Medium | Slow-hawking | Low–moderate | |
| Vespertilionidae | <i>Scotoecus hirundo</i> | Very small | Low | Medium | Moderately fast-hawking | Low | |
| Hipposideridae | <i>Hipposideros vittatus</i> | Very large | Low | High | Fly-catching | Moderate | |
| Rhinolophidae | <i>Rhinolophus hildebrandtii</i> | Medium | Low | Low | Perch-hunting and slow-hawking | Moderate | |
| Rhinolophidae | <i>Rhinolophus fumigatus</i> | Medium–small | Low | Low | Fly-catching, slow-hawking and ? gleaning | Moderate | |
| Rhinolophidae | <i>Rhinolophus blasii</i> | Small | Low | Low | Slow-hawking, fly-catching and gleaning | Moderate–high | |
| Vespertilionidae | <i>Myotis tricolor</i> | Small | Low | Low | Slow-hawking, ? gleaning | Moderate (? also high) | |
| Vespertilionidae | <i>Nycticeinops schlieffeni</i> | Very small | Low | Very low | Slow-hawking | Low–moderate | |
| Rhinolophidae | <i>Rhinolophus clivus</i> | Small | Low | Very low | Slow-hawking, fly-catching and ? gleaning | Moderate | |
| Rhinolophidae | <i>Rhinolophus simulator</i> | Small | Low | Very low | Slow-hawking and ? gleaning | Moderate | |
| Vespertilionidae | <i>Myotis welwitschii</i> | Medium–small | Low | Very low | Uncertain | ? Moderate–high | |
| Vespertilionidae | <i>Pipistrellus rueppellii</i> | Very small | Low | Very low | Slow-hawking mainly over water and marshes | Moderate–high | |
| Vespertilionidae | <i>Myotis bocagii</i> | Small–very small | Low | Very low | Slow-hawking and trawling | Moderate–high | |
| Vespertilionidae | <i>Pipistrellus zuluensis</i> | Very small | Low | Very low | Slow-hawking | Moderate–high | |
| Vespertilionidae | <i>Pipistrellus</i> cf. <i>melckorum</i> | Very small | Low | Very low | Slow-hawking | Moderate–high | |
| Vespertilionidae | <i>Pipistrellus nanus</i> | Very small | Low | Very low | Slow-hawking | Moderate–high | |
| Vespertilionidae | <i>Kerivoula argentata</i> | Very small | Low | Very low | ? Gleaning | Very high | |
| Nycteridae | <i>Nycteris grandis</i> | Medium–small | Very low | Low | Slow-hawking, fly-catching and gleaning | Very high | |
| Nycteridae | <i>Nycteris macrotis</i> | Small | Very low | Very low | ? Gleaning | Very high | |
| Nycteridae | <i>Nycteris thebaica</i> | Small | Very low | Very low | Slow-hawking, fly-catching and gleaning | Moderate–very high | |
| Nycteridae | <i>Nycteris hispida</i> | Small–very small | Very low | Very low | Slow-hawking and gleaning | Very high | |

Intensity. Usually described either as low (<75 dB at 10 cm distance) or high (ca. 100–110 dB at 10 cm). In this context, intensity = sound pressure level.

CF-frequency. The frequency of the CF component; particularly useful when the CF component is the main component of the call (e.g. calls of rhinolophids and hipposiderids).

Start-frequency. Frequency at beginning of call. Because high frequencies attenuate rapidly (and therefore cannot be heard and/or

recorded as far away as lower frequencies), sonograms often do not show the highest frequencies that were emitted by the bat. Therefore start-frequencies appear to be very varied and are of comparatively little use as a means of identifying calls.

End-frequency. Frequency at end of call. For FM calls ending with lower frequencies than their start-frequencies, the end-frequency is an important means of identifying calls.

Peak-frequency. Frequency with maximum energy and intensity. Often

Resource partitioning

The number of species in African bat communities ranges from ten or less (e.g. in some montane habitats) to at least 36. Each bat in a community is adapted to exploit a different combination of resources, and to obtain them in different ways, places or times, so that competition between species is minimal. To achieve this, bats have become almost as diverse as birds in their size, morphology, flying abilities, food and foraging behaviour, dependence on water, day-roosts and other habits (O'Shea & Vaughan 1980, Findley & Black 1983, Aldridge & Rautenbach 1987, Rautenbach & Fenton 1992, Decher 1997). Some of the differences between 26 microbats in a community in Malawi, which enable them to co-exist without excessive competition for resources, are given in Table 9.

Day-roosts and roosting behaviour

Bats are most active at night and they roost during the day. Bats are found in a wide range of day-roosts but few species have identical preferences. Lithophilic species depend on natural day-roosts found in caves, rock-crevices, holes under rocks and boulders, and gaps under exfoliating rock. Some lithophilic species also use man-made structures that have similar characteristics, e.g. mines, culverts, cavernous buildings, and nooks and crannies in buildings. Some also use burrows. Phytophilic species roost in trees or shrubs: among foliage or bare branches, on tree-trunks, under exposed roots, inside furled leaves, in small holes in trunks or branches, or in hollow trunks. Some phytophilic species also use man-made structures that have similar characteristics, including exterior walls of buildings (especially under eaves), and nooks and crannies in and under thatch and other structures. Some use holes made by birds such as woodpeckers (Picidae) and barbets (Capitonidae), or bird-nests such as those of weavers (Ploceidae). Some species are adaptable and tolerant and can use a variety of roosts. Others are limited to roosts where temperature, humidity, light-level, noise-level and proximity to food and water meet particular specifications. Some species roost singly or in monospecific groups of varying size. Others commonly roost with bats of other species. When this happens, in a cave for example, the different species will be found in different parts of the cave if their requirements are dissimilar, but may be found in close contact if their requirements are similar. Tolerance may vary seasonally depending on the special requirements of young or hibernating bats. Because many species have specific roost requirements, conservation plans must include protection of the natural day-roosts, and it is very important that bats in caves are not disturbed – especially if they are torpid or hibernating. Not all bats roost in dark places: some commonly cling to the outside walls of houses and exposed tree-trunks. Some bats move to a different roost every few days; others show varying degrees of roost-fidelity. Roost-fidelity is usually strong in species that roost in caves, hollow trees and buildings that provide permanent sites. In contrast, foliage-roosting bats often show fidelity to a home-area rather than to a specific roost. Some bats show fidelity to one or more roosts, which they use alternately. Roost-fidelity is often strongest during maternity.

Bats roost in several ways. Bats in some families hang from one or both hindfeet, with the toes curled round slender twigs or toe-holds

| Search-phase
Echolocation | Diet |
|---|--|
| Shallow linear FM and shallow sigmoid FM | Hard-shelled beetles and various soft-bodied insects |
| Shallow linear FM | Mainly soft-bodied insects |
| CF and short shallow linear FM | Mainly moths |
| Very shallow linear FM and steep/shallow FM | Mainly beetles; also various other insects |
| Steep FM/QCF | Mainly Diptera; some beetles and moths |
| Steep FM/QCF (in moderate clutter) | Mainly beetles; also various other insects |
| Very shallow linear FM and steep/shallow FM | Not known |
| CF/FM | Mainly hard-shelled beetles |
| FM/CF/FM | Mainly beetles and moths |
| FM/CF/FM | Beetles, moths and other insects |
| FM/CF/FM | Moths |
| Steep linear FM | Not known |
| Steep/shallow FM | Beetles, Diptera and various other insects |
| FM/CF/FM | Moths, small beetles |
| FM/CF/FM | Mainly moths |
| Steep linear FM | Includes beetles |
| Steep FM/QCF | Includes beetles |
| Steep linear FM | Minute insects including moths and beetles |
| Steep FM/QCF | Includes moths and beetles |
| Steep FM/QCF | Not known |
| Steep FM/QCF | Mainly small beetles and moths |
| Whispering | Not known |
| Whispering | Small vertebrates, insects |
| Whispering | Orthoptera, beetles, termites |
| Whispering | Various insects (opportunistic) |
| Whispering | Small moths and other small insects |

analysed by computer software and particularly useful as a means of identifying calls.

Call-duration. The duration (in ms) of each call (= pulse) within a sequence of calls. Sometimes means and ranges are given, sometimes only maximum durations.

Intercall-interval. The interval (in ms) between successive calls in a sequence of calls.

on rough surfaces. The weight of the bat's body causes tendons in the hindlimbs to pull the toes into the curled position so that hanging is effortless but the bat must exert effort to release its grip. Bats may hang freely, or in contact with vertical surfaces such as walls or tree-trunks. Some species always hang freely; others hang either freely or in contact. Some species hang apart (with no contact with other bats) while other species huddle together in tight clusters. Bats in other families do not hang: instead they either crouch on surfaces that are horizontal, or cling (head down) to surfaces that are sloping or vertical. In both cases, they hold on with their thumbs as well as their hindfeet. Some species crouch or cling on exposed surfaces; others tuck themselves into crevices. Some crouch or cling apart; others huddle. Most bats fold their wings against the sides of their bodies, but pteropodids, rhinolophids and hipposiderids wrap them around the body.

Torpor and hibernation

Daily torpor

Bats are warm-blooded and, because they are small, they require a great deal of food to maintain a high constant temperature at all times, even in the tropics. Because of this, some species of microbats do not attempt to maintain a constant temperature. Instead, during the day, these bats go into torpor, allowing the body temperature to fall from around 34–39°C to approximately the ambient temperature. Torpid bats move very sluggishly and are unable to fly, but they are perfectly healthy. At dusk, they warm themselves up by shivering, a process that takes ca. 20 minutes. When they become warm enough, they become active, investigate their surroundings, yawn, communicate with their neighbours, and indulge in long sessions of meticulous grooming before taking off to forage for food. Only one African megabat, *Megaloglossus woermanni*, is known to enter torpor. In contrast, one or more species of African microbats in each of the families Rhinolophidae, Hipposideridae, Rhinopomatidae, Emballonuridae, Molossidae and Vespertilionidae becomes torpid during the day.

Hibernation

In temperate regions (including those in North Africa and South Africa), when temperatures are low and flying insects very scarce during 'winter', many microbats spend most of the time (day and night for many days) in a deep state of torpor referred to as hibernation. During this time, they slowly metabolize large reserves of fat that are laid down during the autumn. Bats also accumulate reserves of brown fat in autumn, and deposits of the two kinds of fat can result in a bat's weight being 20–30% higher in autumn than in spring. The brown fat is used if and when bats arouse themselves during the hibernation period – which they do occasionally in order to urinate, defecate, drink, feed or move to a more favourable roost. Arousal also occurs if bats are disturbed during hibernation and, because the precious reserves of fat are depleted each time this happens, bats are unable to survive if they are disturbed more than a very few times. Consequently, populations may be endangered by excessive disturbance of large numbers of bats at the roosts where they are hibernating. Roosts used during hibernation are called hibernacula. Invariably, hibernacula must be very humid to

prevent the bats becoming dehydrated, and often hibernating bats glisten with droplets of water that have condensed on their pelage. Furthermore, each species requires a particular ambient temperature for hibernation. For this reason, roosts used as hibernacula are often different to the day-roosts used in summer, and hibernacula such as caves and other underground cavities are often occupied by several species of bats, which may choose to hibernate in different parts (with different temperatures) if their temperature preferences are different. During hibernation, bats often huddle together and usually adopt special postures to reduce the area of their body surface; both facilitate the conservation of energy and water. Their heart-rates drop to as low as 18–80 beats/min (cf. as high as 880 beats/min when active) (E. Kulzer in Schober & Grimmberger 1989), and there can be as much as 60–90 min between breaths of air. Furthermore, hibernating bats are almost incapable of body-movement, so it is easy to think that they are dead. In North Africa, hibernation has been observed in 12 species (*Rhinolophus euryale* and two other rhinolophids, *Tadarida teniotis*, *Barbastella barbastellus*, *Nyctalus leisleri*, *Pipistrellus pipistrellus*, *Myotis capaccinii* and other species of *Myotis*, and *Miniopterus schreibersii*). In South Africa, hibernation has been observed in five species (*Rhinolophus capensis*, *R. clivosus*, *Myotis tricolor*, *Miniopterus fraterculus* and *M. natalensis*).

Drinking, water balance and kidneys

Bats, like other mammals, must balance water loss (mainly from evaporation, urination and defaecation) with water obtained by drinking water, eating moist foods and metabolizing fats and carbohydrates. For bats, evaporative water loss during flight is extremely high: in one species it is 3.1% body weight/h compared with 0.05% during rest (Carpenter 1969). The rate of water loss through the kidneys varies greatly, depending on the amount of waste products that need to be excreted and on the urine-concentrating ability of the kidney. Megabats obtain copious amounts of water from their food, and their diet is low in protein and salts. Their kidneys excrete large volumes of very dilute urine while maximally retaining valuable solutes, and their faeces are moist. For example, *Rousettus aegyptiacus* produces urine concentrations ranging from 88 to 1800 mOsmol/kg. It is unlikely that megabats need to drink once they have started to feed but those that roost in sunny or windy places probably need to drink soon after leaving their roosts, especially if their feeding-grounds are far away. Some species usually roost near water, and some species skim over water, dip into it and presumably drink although this has not been confirmed (Bergmans 1978). Some flying-foxes (including *Pteropus seychellensis*) sometimes drink seawater, possibly to obtain salts. In contrast to megabats, insectivorous microbats obtain much less water in their diet, and need additional water to excrete waste products. Although they obtain some water by metabolizing fat from insects, it is predicted that they also need to drink, and many species come to pools and rivers presumably for this purpose. Insectivorous microbats produce dry faeces and their kidneys conserve water by producing concentrated urine. Mean maximum urine concentration can be predicted reliably from the ratio of cortex width to medulla length, which is very variable (Figure 29); the longer the medulla relative to the width

Figure 29. Outlines of mid-sagittal sections of kidneys from Malawian bats and, in brackets, the predicted mean maximum urine concentration ranking for the microbats. (a) *Epomophorus wahlbergi* (fruit-bat), (b) *Pipistrellus zuluensis* (very high), (c) *Nycticeinops schlieffeni* (very high), (d) *Taphozous mauritanus* (high), (e) *Laephotis botswanae* (medium), (f) *Hipposideros ruber* (low), (g) *Rhinolophus clivosus* (low), (h) *Nycteris thebaica* (low) and (i) *Tadarida condylura* (very low). Cortex in black. In (a) entire medulla lightly stippled. In others, outer zone of medulla lightly stippled, inner zone of medulla heavily stippled. Based on Happold & Happold (1988).

of the cortex, the more concentrated the urine can be (Geluso 1980). In 28 species of microbats, representing five families, which live in diverse African habitats, predicted mean maximum urine concentration ranges from 2298 to 4709 mOsmol/kg (Happold & Happold 1988). This is comparable with the range 2390–5010 mOsmol/kg, determined from water deprivation experiments or predicted from renal morphology, for 27 species of insect-eating microbats from elsewhere (Geluso 1980). Efficient water-conserving kidneys are probably particularly advantageous to species that do not drink during sustained periods of torpor or hibernation. Although some desert microbats have efficient water-conserving kidneys, some do not: the ability of bats to live in desert habitats, and also to roost in hot dry day-roosts, seems to depend on their ability to fly to sources of water and not on their ability to reduce urinary water loss (cf. desert rodents).

Distributions, habitats and species richness

Profiles include a distribution section in the text as well as a map. Both must be consulted for a complete record of known localities because the text sometimes includes localities that are not mapped.

Bats are found throughout Africa with the exception of some extremely hot and dry desert regions (where water, food and/or cool day-roosts are limiting factors) and the tops of high mountains (where food, day-roosts and low temperatures are limiting factors). Of the 220 species in Africa (excluding *Mormopterus acetabulosus*, *M. francoismoutoui*, *Pipistrellus permixtus* and *Phoniscus aerea*, which are not likely to be true residents of Africa), 65% are found only or mainly in the tropics, 25% inhabit both tropical and temperate habitats, and 10% are found only in temperate habitats. Of the 22 temperate species, only *Rhinolophus capensis* and *Cistugo lesueuri* are found in southern Africa, and most of those found in North Africa are Palearctic species that extend into Africa across the Mediterranean Sea, or via the Middle East. Some species are found in many biotic zones and are distributed very widely. Of the 220 species for which data are available, 9% are found only in the coastal

and/or montane habitats of the Maghreb and Cyrenaica in North Africa. Elsewhere, 24% occur only in forests (rainforests, montane and riverine forests), 25% in both forests and savannas, 28% only in savannas, 7% in savannas and arid zones, 4% only in arid zones (where food and suitable day-roosts are available), 2% are able to exploit forest, savanna and arid habitats and 1% are island specialists. Ninety-two species (42%) are able to exploit montane habitats, but only two rhinolophids and six vespertilionids have been found only in montane habitats. Although all bats can fly, they vary in how far they can fly without resting and how easily they can orientate and travel across unfamiliar or inhospitable terrain. Consequently, the distributions of some species are restricted by geographical barriers such as drought corridors, the Dahomey Gap and other belts of unfavourable habitat (natural or man-made), the Rift Valleys and the Lower Zambezi Valley, and some of the largest rivers. In contrast, the distributions of many species have been extended by corridors of suitable habitat such as riverine and gallery forests in savannas. Because the requirements of bats may have patchy distributions, or vary seasonally, the bats themselves may have patchy distributions, and distribution maps often give a misleading impression that species are more widely distributed than they are in reality.

For species with wide distributions, the sources of locality records are too numerous to list in the profiles. In many of these cases, the major sources are country checklists and surveys including the following. **Algeria:** Kowalski & Rzebik-Kowalska 1991. **Angola:** Crawford-Cabral 1986. **Benin:** Robbins 1980. **Botswana:** Smithers 1971. **Burkina:** Koopman *et al.* 1978, Koch-Weser 1984. **Burundi:** Kock 1980, Verschuren 1980. **Cameroon:** Aellen 1952, Perret & Aellen 1956, Eisentraut 1973a. **Central African Republic:** Schlitter *et al.* 1982, Lunde *et al.* 2001. **Chad:** Viellard 1974. **Congo:** Aellen & Brosset 1968, Dowsett *et al.* 1991. **Côte d'Ivoire:** De Vree 1971, Lim & Van Coeverden de Groot 1997. **Djibouti:** Pearch *et al.* 2001. **DR Congo:** Hayman *et al.* 1966. **Egypt:** Gaisler *et al.* 1972, Qumsiyeh 1985. **Equatorial Africa (Bioko I.):** Eisentraut 1964, 1973a, Juste & Ibáñez 1994. **Equatorial Africa (mainland):** Jones 1971. **Ethiopia & Eritrea:** Lagen *et al.* 1974, Yalden *et al.* 1996. **Gabon:** Brosset 1966. **Gambia and Ghana:** Grubb *et al.* 1998. **Guinea:** Veiga-Ferreira 1948, 1949, Eisentraut & Knorr 1957. **Guinea-Bissau:** Monard 1939. **Kenya:** Aggundey & Schlitter 1984, Schlitter *et al.* 1986. **Lesotho:** Lynch 1994. **Liberia:** Kuhn 1965, Koopman 1989, Koopman *et al.* 1995. **Libya:** Qumsiyeh & Schlitter 1982. **Malawi:** Happold *et al.* 1987, Ansell & Dowsett 1988, Happold & Happold 1997. **Mali:** Meinig 2000. **Morocco:** Aulagnier & Thévenot 1986, Benda *et al.* 2004d. **Mozambique:** Smithers & Lobão Tello 1976. **Namibia:** Shortridge 1934. **Niger:** Braestrup 1935. **Nigeria:** Happold 1987. **Senegal:** Adam & Hubert 1972, Verschuren 1982. **Sierra Leone:** Grubb *et al.* 1998. **Somalia:** Funaioli 1971, Varty & Hill 1988. **South Africa:** Herselman & Norton 1985, Smithers 1983, Taylor, P. 1998, 2000. **Sudan:** Kock 1969a, Koopman 1975, McLellan 1986. **Swaziland:** Monadjem 1998a. **Tanzania:** Swynnerton & Hayman 1951, Kulzer 1962, Cockle *et al.* 1998. **Togo:** De Vree *et al.* 1969, 1970, De Vree & Van der Straeten 1971, Robbins 1980. **Tunisia:** Aellen & Strinati 1969. **Uganda:** Kityo & Kerbis 1996. **Zambia:** Ansell 1978. **Zanzibar I., Pemba I. and Mafia I.:** Moreau & Pakenham 1940, Kock & Stanley 2009. **Zimbabwe:** Smithers & Wilson 1979, Hutton 1986, Cotterill 1996a, b, 2001b, c, 2002b. A great many other localities

have been obtained from other literature and museum specimens, and all maps were reviewed at a Global Mammal Assessment workshop, held in Jan 2005, and attended by ca. 40 mammalogists currently working on bats and/or small mammals in Africa. Since the profiles were submitted in 2006, new locality records have been published. If the new records significantly change the distribution of a species, they are now mentioned in the species profile but it was not possible to update the maps. For this reason, and others, the distribution sections in the profiles often contain localities that are not shown on the maps.

Species richness is greatest in areas where there are diverse day-roosts for both phytophilic and lithophilic bats, abundant food of different sorts, and diverse habitats suitable for species with different foraging strategies. On a broad scale, it seems that there are usually more species near the Equator than at higher latitudes, as roughly indicated by the following examples: 57 species in savanna at 08°45'N in Comoe N. P., Côte d'Ivoire (Fahr & Kalko 2011), 51 species at ca. 07°40'N on Mt Nimba, in Guinea, Côte d'Ivoire and Liberia (A. Monadjem pers. comm.), 40 species in rainforest at 05°50'N in Tai N. P., Côte d'Ivoire (Fahr & Kalko 2011), although only 25 species in thorn scrub at 02°18'S at Masalani, near Kibwezi, Kenya (O'Shea & Vaughan 1980). For comparison, there are 27 species in miombo woodland at 15°02'S in Liwonde N. P., Malawi (Happold & Happold 1997), and ca. 36 species in diverse woodlands at ca. 18°S at Sengwa Wildlife Research Area in Zimbabwe (Fenton 1985). However, climate, habitat diversity, the area included in the locality, differences in sampling methods and in the amount of time spent sampling, mean that these data give only a rough estimate of latitudinal variation in species richness.

Localized movements, migration and nomadic movements

Localized movements

These occur when bats fly within part or all of their home-ranges within a single night or within a limited period of time. They include movements between different day-roosts, which are used during a particular season, and foraging flights from the day-roosts. Some fruit bats routinely fly 10 km from their day-roosts to their foraging-grounds and another fruit bat, *Eidolon helvum*, forages as far away as 59 km from the day-roost when not migrating (Richter & Cumming 2008). Molossids, which fly very fast (e.g. 27 m/sec) for most of the night, must also travel long distances although not necessarily so far from their day-roosts.

Migration

This describes the movements of species that travel predictably, and more-or-less directly, from one habitat to another (and back again) along predetermined routes, in response to seasonal changes in climate, food supply or any other resource. Migrating species do not migrate continuously. Some fruit bats, including *Eidolon helvum*, *Myonycteris torquata* and *Nanonycteris veldkampii* (see species profiles) migrate from the Rainforest–Savanna Mosaic to savanna zones (such as the Guinea Savanna BZ in West Africa), and then back again. In West Africa, round-trip distances of at least 750 km have

been reported for *Myonycteris torquata* and *Nanonycteris veldkampii* (see species profiles), and *Eidolon helvum* is reported to travel round-trip distances of ca. 1500 km in West Africa (Thomas 1983). Elsewhere, *E. helvum* ♂♂ travel at least 2000 km in three months, from NC Zambia to N DR Congo (Richter & Cumming 2008). In West Africa, the migration of fruit bats follows the rains associated with the Intertropical Convergence Zone, which oscillates north and south, creating bimodal peaks in rainfall in the Rainforest–Savanna Mosaic, and a unimodal peak in the Guinea Savanna BZ. In contrast, other West African fruit bats apparently do not migrate and therefore there are resident or nomadic populations of these species either in the rainforest, or in the savannas, throughout the year. Thomas (1983) investigated the seasonal migrations of the four fruit bats listed above, and suggested that the seasonality of fruit production, population levels of the resident species and the levels of competition for food resources may interact to create the conditions necessary for migration. He suggested that the high amplitude of the seasonal fluctuations in abundance of fruit in savanna habitats creates a wet-season surplus of food, which results in low intra-specific and inter-specific competition levels in these habitats compared with the levels in the rainforest where fluctuations in the abundance of food are of much smaller amplitude. Migration driven by the search for food is sometimes referred to as alimentary migration.

Several species of African microbats are also migratory, but often for reasons different to those of fruit bats. For example, in South Africa, some species migrate from warmer regions where they roost in summer to cooler regions where they can find the conditions enabling them to hibernate during the winter; these species include *Rhinolophus simulator*, *Nycteris thebaica*, *Myotis tricolor*, *Miniopterus fraterculus* and *M. natalensis* (see species profiles). Most species of North African bats are also reported to migrate between summer- and winter-roosts – in Europe if not in Africa. In East Africa, it has been suggested that some species avoid the long dry season (Oct–Dec) and associated shortage of insects experienced in inland lowland localities by migrating to coastal or montane habitats that receive rain during this period; these alimentary migratory species include *Hipposideros vittatus*, *Taphozous hildegardeae* (but not all populations) and *Scotoecus hirundo* (see species profiles).

An interesting consequence of migration in bats is that two taxa may be sympatric during part of the year and allopatric during another part, and unless the time of mating is known, it is impossible to determine whether or not these two taxa have an opportunity to interbreed (Koopman 1983). As reproductive isolation is the crux of the biological species concept, when taxa are raised to specific status on the grounds that they are geographically isolated, it is important to be certain that migratory patterns do not bring the taxa together sympatrically during their mating seasons when interbreeding would be possible. Conversely, two taxa could be sympatric for much of the time, but geographically isolated during the mating period and therefore reproductively isolated.

Nomadic movements

Unlike migration, nomadic movements are unpredictable and irregular, and are undertaken by species that live in unpredictable habitats (Delany & Happold 1979). They do not occur at any particular season, or at yearly intervals, and the direction and

extent of nomadic movements vary according to local conditions. Within fairly localized areas in savannas and arid zones, and even in rainforests, trees flower and fruit at different times in neighbouring areas depending mainly on where and when localized rainfall occurs, and this drives nomadic movements by some fruit bats. African fruit bats that are thought to be nomadic include *Epomophorus crypturus*, *E. gambianus*, *E. wahlbergi* and *Megaloglossus woermanni* (see species profiles). Vagaries of rainfall also create unpredictable rises and falls in the abundance of insects in neighbouring areas as, for example, when a local downpour stimulates the emergence of flying termites in that area. However, as yet there appear to be no documented accounts of nomadic movements in African microbats.

Social and reproductive behaviour

Very little is known about the social behaviour of most species, and most of our knowledge comes from observations of a few species at their day-roosts. Some species of bats are solitary. Other species live in pairs (i.e. one ♂ with one ♀) or monogamous family groups, some form harems (one ♂ with two or more ♀) and some live in groups of other kinds. Groups range in size from three to many thousands of individuals and sometimes several millions (e.g. five million *Eidolon helvum* at one locality in Zambia). Following Ansell (1960a), groups are described as small (3–15), medium (15–30), large (30–100), or very large (more than 100). Some groups are comprised of roughly equal numbers of ♂♂ and ♀♀, while others may be comprised mainly or solely of ♂♂ or of ♀♀. Some species spend the dry seasons or winters in groups of adult ♂♂ and ♀♀, but form maternity colonies comprised of pregnant ♀♀ and/or lactating ♀♀ and their young in the warmer, wetter months.

Bats interact with each other in many ways. They communicate with vocalizations (many of them audible to humans), and with olfactory, tactile and occasionally visual signals. Bats that belong to groups recognize each other and may roost and forage together. Individuals that are not recognized may be threatened with specific vocalizations, swiped by the claw of a thumb, or they may be pursued, attacked and bitten. Many species defend feeding territories and/or roosts. Although group-members may roost together, many maintain some distance between themselves and their nearest neighbour; this space may be established and maintained with vocal protest and jostling. Territorial disputes for the best places are a common occurrence and the outcome may influence mate-selection.

Compared with other mammals, little is known about the reproductive behaviour and social organizations of bats, but there are some notable exceptions and several types of social organization and mating systems have been defined (e.g. Bradbury & Vehrencamp 1976, Emlen & Oring 1977, Bradbury 1979, 1981). These include (with African examples):

Monogamy. One ♂ mates with one ♀ and that ♀ only mates with that ♂ (e.g. *Hipposideros beatus*, *Lavia frons*).

Polygyny. One ♂ mates with several ♀♀. Polygynous social organizations and mating systems include harem-formation (one ♂ resides with and mates with a stable group of ♀♀). Harem-

formation may be based on the defence of a group of ♀♀ (female-defence polygyny) as in *Coleura afra*, or on the defence of one or more resources (e.g. roosts and/or foraging areas) to which small groups of ♀♀ are attracted (resource-defence polygyny) as in *Pipistrellus* cf. *helios*, or a combination of both as in *Taphozous hildegardeae*, *Tadarida pumila* and *Myotis bocagii*, and perhaps *Otomops martiensseni*.

Promiscuity. Each ♂ mates with several ♀♀ and each ♀ with several ♂♂ (e.g. *Pipistrellus nanus*). This possibly gives rise to sperm competition (Fenton 1984, Bernard *et al.* 1997).

Classical lekking. Defined loosely, ♂♂ aggregate at traditional sites (leks), compete for a status or position that conveys maximal attractiveness to ♀♀, and display to attract ♀♀. Receptive ♀♀ visit the lek and mate with the ♂ of their choice. For the crucial definitive criteria of classical lekking, see Bradbury (1977) and *Hypsignathus monstrosus* (species profile). Leks are widely spaced, and within leks, the ♂♂ are clustered in fairly close proximity to each other. Lekking allows ♀♀ to examine a large number of ♂♂ in the least possible time, and enables younger ♀♀ to benefit from the knowledge of how older ♀♀ have selected their mates (Bradbury 1981).

Exploded lekking. Described as an intermediate stage in the evolution of lekking (Bradbury 1981). Similar to classical lekking except that exploded leks are not so widely spaced, and within exploded leks, the ♂♂ are not so close together. Nevertheless, the ♂♂ are aggregated to some extent – an essential criterion of exploded lekking is that the sites at which individual ♂♂ display are not uniformly dispersed.

Life-histories and reproductive strategies

Most small mammals have 'live fast – die young' life-histories characterized by short life-spans, rapid reproduction and high mortality. In contrast, bats 'live slow and die old' – their life-histories are characterized by longevity (as much as 30 years in the wild), many reproductive events in a life-time, small litter-sizes and delayed onset of sexual maturity (Barclay & Harder 2003, Barclay *et al.* 2004). The evolution of nocturnal flight has been a key factor in shaping the life-histories and reproductive strategies of bats for two main reasons – first because it reduces predation and hence mortality rate, and second because flight dictates that young bats must be large enough and developed enough to fly before they are weaned, and this means that lactation periods (which are energetically costly) must be relatively long (1–3 months) (Pomeroy 1990, Barclay 1994).

Reproductive strategies are determined primarily by litter-size and reproductive chronology. Most bats are monotocous (litter-size one: twinning abnormal), but some are polytocous (litter-size normally or often more than one). In Africa, litter-size is known for 103 species: 83% are normally monotocous, 17% are normally or often polytocous. These polytocous species include 12 species (all vespertilionids) that normally or very often have twins, and two species (*Nycticeinops schlieffeni*, *Scotophilus dinganii*) that usually have 2–3 young/litter. In Africa, polytocous has been observed only in the families Pteropodidae and Vespertilionidae. Of 19 pteropodids for

which information is available, polytocry (as a normal strategy) has been reported in only one species (*Epomops dobsonii*), but 48% of the 31 African species of vespertilionids for which data are available are often or normally polytocous. In bats, litter-size is limited by the constraints of flight, and also by the energetic demands of long lactation periods. In Africa, most of the polytocous species have mean weights <10 g, but three notable exceptions are *Scotophilus viridis* (16.5 g), *S. leucogaster* (19.7 g) and *S. dinganii* (23.9 g). This could be because smaller species can carry relatively larger weights while flying (Aldridge & Brigham 1988). In Africa, polytocry is only known to occur in species that are monoestrous (each ♀ has one litter/year), with the possible exception of *Myotis bocagii*.

Reproductive chronologies are defined by the number of litters/year and the timing of reproductive events. Events (e.g. mating and giving birth) are said to be 'seasonal' if they occur only at particular times of the year (e.g. in mating-seasons and parturition-seasons). Consequently, a reproductive chronology can be described, for example, as 'restricted seasonal monoestry' if all young in a specified area are born during a short parturition-season. Seasonal events in reproductive chronologies are usually, but not always, linked to seasonal changes in climate and the availability of resources, but 'seasonal' in the context of a reproductive chronology is not the same as 'seasonal' in the climatic sense. Females may be monoestrous (each ♀ has one litter/year) or polyoestrous (each ♀ has more than one litter/year). For 67 African species for which valid data are available, polyoestry has only been recorded in 22 species (34%); these include 7 of 9 species of pteropodids, 3 of 4 species of emballonurids, 2 of 3 species of nycterids, 6 of 9 species of molossids and 3 of 24 species of vespertilionids. The reproductive chronologies of 51 species are known for at least one locality within their geographic ranges in Africa. Thirty-seven (73%) of these species have only been reported as monoestrous, 12 (24%) have only been reported as polyoestrous and two (*Epomophorus wahlbergi*, *Rousettus aegyptiacus*) are monoestrous in some localities and polyoestrous in others. Bernard & Cumming (1997) suggest that polyoestry is the ancestral strategy of bats, with monoestry evolving as an adaptation to higher latitudes where conditions are optimal only once per year. In Africa, most polyoestrous species have two litters/year, but *Tadarida pumila* has three, four or five litters/year depending on locality. Polyoestry is not easy to prove and the literature on African bats contains many cases where polyoestry has been suggested, implied or claimed on the basis of evidence that is inappropriate and invalid. Here, following Happold & Happold (1990a), a species is said to be polyoestrous only if one or more of the following observations have been made at one locality: (1) the observation of two or more births/year in marked or captive individuals, (2) the simultaneous occurrence of pregnancy and lactation (which also indicates postpartum oestrus), (3) observation or evidence of copulation while the ♀ is still lactating, (4) histological confirmation of postpartum oestrus, (5) the occurrence of pregnancy with evidence of very recent lactation and (6) the observation that 80% or more of the ♀♀ in a population were pregnant during each of two or more breeding seasons within one year. The occurrence of births in two or more seasons (without any of the above observations) is not considered to be proof of polyoestry: alternative explanations include the possibilities that there are monoestrous bats with austral and boreal cycles at that

locality, or that there are two species involved. Conclusions have not been drawn from data that come from several localities because the timing of reproduction in different localities is not necessarily the same. This is especially true of localities north and south of the Equator where seasons are six months out of phase.

Ten reproductive chronologies have been observed in African bats (Happold & Happold 1990a) and their characteristics are illustrated schematically in Figure 30. Note that the black bars in this illustration represent the periods during which ♀♀ are pregnant (not the periods in which rain falls as erroneously indicated by Racey & Entwistle 2000).

(a) *Restricted seasonal monoestry*. Each ♀ has one litter/year. Females are in close or fairly close reproductive synchrony and therefore all young are born at the same time each year. The season of parturition may vary from a few days to not more than two months and is restricted to one climatic season or the transition between two climatic seasons. E.g. *Eidolon helvum*, *Rhinolophus capensis*, *Hipposideros caffer*, *Nycteris thebaica*, *Pipistrellus nanus*, *Miniopterus natalensis* and many others.

(b) *Extended seasonal monoestry*. Each ♀ has one litter/year. Females are not in close reproductive synchrony, the single season of parturition is 2–7 months and may span more than one climatic season. E.g. *Rousettus aegyptiacus* and *Rhinolophus blasii*.

(c) *Aseasonal monoestry*. Each ♀ has one litter/year. Females are not in reproductive synchrony and young are born in eight or more months of the year and in all climatic seasons, e.g. perhaps *P. nanus* in some equatorial habitats (Happold & Happold 1990b), but this needs confirmation because the available data perhaps came from different cryptic species.

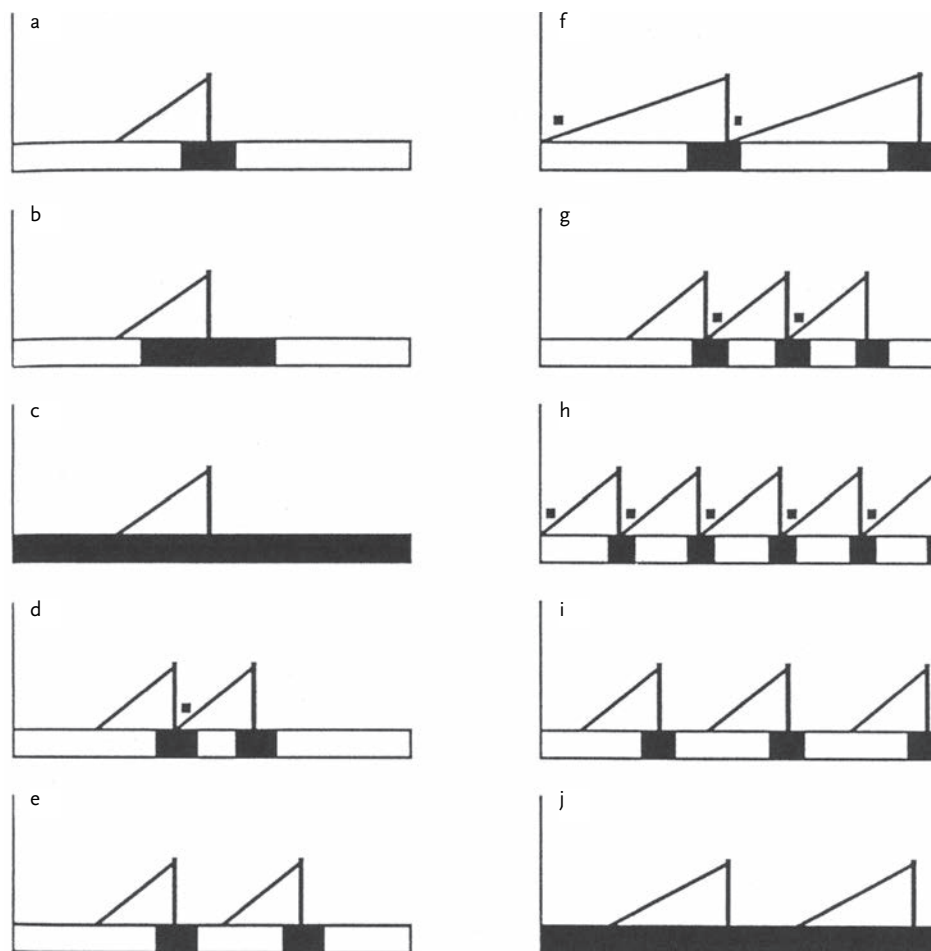

(d) *Seasonal bimodal polyoestry with postpartum oestrus*. Each ♀ has two litters/year. Females are in reproductive synchrony and therefore young are born in two distinct seasons of parturition that usually occur during one climatic season. The first birth is followed by a postpartum oestrus and a period of simultaneous pregnancy and lactation. The second birth is followed by lactation only, and then a period of reproductive inactivity. E.g. *Tadarida condylura* in Malawi.

(e) *Seasonal bimodal polyoestry without postpartum oestrus*. Each ♀ has two litters/year. Females are in reproductive synchrony and therefore young are born in two distinct seasons of parturition. Neither birth is followed by a postpartum oestrus. In all known examples, seasons of parturition occur during similar climatic seasons (e.g. in each of two wet seasons where rainfall is bimodal). E.g. *Tadarida condylura* and *T. pumila* in Kenya, and *T. thersites* in Uganda.

(f) *Continuous bimodal polyoestry with postpartum oestrus*. Each ♀ has two litters/year and a gestation of 5–6 months. Females are in reproductive synchrony and therefore young are born in two distinct seasons of parturition ca. six months apart. Each parturition is followed by a postpartum oestrus. Seasons of parturition do not necessarily coincide with a particular climatic season. E.g. *Epomophorus wahlbergi*, *Epomops buettikoferi*, *E. franqueti*, *Hypsignathus monstrosus*, *Micropteropus pusillus* and *Rousettus aegyptiacus*.

Figure 30. Schematic illustrations of the reproductive chronologies of African bats (after Happold & Happold 1990a). In each illustration, the horizontal axis covers 12 months. Sloped lines indicate pregnancy in one individual, and vertical lines indicate parturition in that same individual. Black bars indicate the season(s) of parturition in one population as a whole: they do not indicate periods of rainfall. ■ = postpartum oestrus. The duration of pregnancy and season of parturition varies according to species and locality.

(a) Restricted seasonal monoestry. (b) Extended seasonal monoestry. (c) Aseasonal monoestry. (d) Seasonal bimodal polyoestry with postpartum oestrus after first parturition. (e) Seasonal bimodal polyoestry without postpartum oestrus. (f) Continuous bimodal polyoestry (note postpartum oestrus after both parturitions). (g) Seasonal multimodal polyoestry with postpartum oestrus after all but the last parturition in the season. (h) Continuous multimodal polyoestry with postpartum oestrus after every parturition. (i) Continuous multimodal polyoestry without postpartum oestrus. (j) Aseasonal polyoestry. This could theoretically occur with or without postpartum oestrus: the latter is illustrated here.

(g) *Seasonal multimodal polyoestry with postpartum oestrus*. Each ♀ has three or more litters/year, with a postpartum oestrus after all except the last birth, which is followed by a period of reproductive inactivity. Females are in reproductive synchrony and therefore young are born in distinct seasons of parturition all (or most) of which occur during one climatic season. E.g. *Tadarida pumila* in Malawi and South Africa. (Seasonal multimodal polyoestry without postpartum oestrus has not been observed.)

(h) *Continuous multimodal polyoestry with postpartum oestrus*. Each ♀ has three or more litters/year with a postpartum oestrus after every birth. Females are in reproductive synchrony and therefore young are born in three or more distinct seasons of parturition. The seasons of parturition are not restricted to one climatic season. E.g. some *Tadarida pumila* in Ghana.

(i) *Continuous multimodal polyoestry without postpartum oestrus*. Each ♀ has three or more litters/year; none of the births is followed by a postpartum oestrus. Females are in reproductive synchrony and therefore young are born in three or more distinct seasons of parturition. The seasons of parturition are not restricted to a particular climatic season. E.g. *Tadarida pumila* in Uganda.

(j) *Aseasonal polyoestry*. Each ♀ has two or more litters/year. Females are not in reproductive synchrony and young are born in eight or more months of the year and in all climatic seasons. (Theoretically,

this chronology could occur with or without postpartum oestrus but, as yet, the only species that perhaps exemplifies this strategy is *Nanonycteris veldkampii* (see species profile), but this needs confirmation.

Bimodal monoestry has been suggested for *Scotonycteris zenkeri* (see species profile) but the data come from different localities and were collected in different years, so this strategy needs confirmation.

Because spermatogenesis, pregnancy and particularly lactation are energetically costly, it is best if they occur when food is most abundant, and these reproductive events tend to be timed with greater force and precision in habitats where food is abundant during one season but scarce at other times. Often it is impossible for both spermatogenesis and lactation to occur when food is most abundant unless the gestation period (defined in this context as the time between mating and parturition) is made substantially longer than the minimum time for normal development of the embryo (Bernard & Cumming 1997, Racey & Entwistle 2000). However, bats exemplify three mechanisms of reproductive delay, which make this possible:

Delayed fertilization combined with sperm storage. Spermatogenesis and lactation occur in summer (or wet season). Sperm is then stored in the cauda epididymides of ♂♂ until autumn (or cool dry season) when mating occurs after the young have been weaned for a few weeks. Sperm is then stored in the female reproductive tract (as well

as cauda epididymides) throughout the winter (when hibernation may occur) or the dry season. In the spring (or late dry season), ovulation, fertilization and implantation occur, uninterrupted development of the embryo takes place, and the young is born in the summer (or early wet season). This is the most common reproductive delay. In Africa, reproductive delay achieved by storage of sperm in the reproductive tract of the ♀♀ has been recorded in *Rhinolophus clivosus*, *R. simulator*, *Nycticeinops schlieffeni* and *Pipistrellus nanus*. It also occurs in European populations of *R. ferrumequinum* and *R. hipposideros* (no data from Africa).

Delayed implantation. Spermatogenesis and lactation occur in summer; ovulation, mating and fertilization occur in autumn. Development begins but the blastocyst does not implant and develop any further until the spring when implantation occurs and development proceeds, usually without any further interruption, until the young is born in early summer. Delayed implantation has been recorded in *Eidolon helvum*, *Rhinolophus landeri*, *Taphozous hildegardeae*, *Miniopterus fraterculus*, *M. natalensis*, probably *M. minor* and, extraliminally, *M. schreibersii*.

Retarded embryonic development. Spermatogenesis and lactation occur in summer; ovulation, mating, fertilization and implantation occur in autumn, then the implanted embryo enters a period of retarded (slowed) growth, which may last 4–8 months, after which development proceeds normally and the young is born in early summer. In some extralimital species, the delay is not a facultative response to low temperatures or shortage of food but, in Africa, retarded development seems to be facultative. It has been recorded in *Hipposideros caffer*, *H. ruber*, *Coleura afra* and *Miniopterus natalensis*.

The timing of reproductive events is usually determined by seasonal changes in the availability of food. For example, a comparison of year-round rainfall, insect abundance and the timing of parturition, at different latitudes in Africa, showed that insect abundance peaks ca. one month after the peak rainfall, and that microbats (with the possible exception of molossids) commonly give birth one month before peak rainfall, presumably so the young bats are newly weaned at the time when insects are most abundant (Cumming & Bernard 1997). It is not surprising, therefore, that intra-specific variations in reproductive strategy have been observed in species that live in diverse environments. Intra-specific variation can be achieved by changes in litter-size, changes in chronology, or both. Intra-specific variation has been observed, for example, in *Epomophorus wahlbergi*, *Rhinolophus blasii*, *Rousettus aegyptiacus*, *Hipposideros caffer*, *Miniopterus fraterculus*, *Miniopterus natalensis*, *Pipistrellus nanus*, *Tadarida condylura* and *T. pumila*.

Relative to other mammals, newborn bats are enormous (Tuttle & Stevenson 1982). They may weigh 15–33% of their mother's postpartum weight. Neonates of megabats are often well furred and have their eyes open. Neonates of microbats are usually pink and naked and their eyes are usually closed; pigmentation appears within a few hours and pelage within a few days. In all bats, the wings are small and crumpled at birth, but reach near adult-size before weaning. Neonates have recurved milk-teeth and disproportionately large thumbs and feet, which enable them to cling tenaciously to the nipples, fur and pubic nipples (if present) of the mother. Usually

after a few days, the young are left at the roost while their mothers forage. Young microbats emit 'isolation calls' when left behind; these are audible to humans until the bat's voice breaks and then the calls of most species become wholly ultrasonic. The ability to echolocate develops before microbats learn to fly. Juveniles are suckled for 1–3 months, until they approach adult size and learn to fly and obtain food for themselves. Volant young may accompany their mothers to learn how and where to forage and how to find the way back to the day-roost. These young bats can be distinguished from adults by the presence of whitish cartilaginous epiphysal plates at the ends of the finger bones, which give the joints a knobby, whitish appearance. Females of monoestrous species usually reach sexual maturity during their first year, and breed during the next breeding season; ♂♂ often take a year longer.

Predators, parasites and diseases

The main predators of African bats are humans, Bat Hawks *Macheiramphus alcinus* and other raptors, owls, hornbills, shrikes, snakes, genets (*Genetta* spp.) and other small carnivores. Bat Hawks have large eyes and a large gape and are specialist bat-eaters, but regular hunting of flying bats at dusk, and sometimes after dark, has also been recorded for African Goshawk *Accipiter tachiro*, Little Sparrow-hawk *A. minullus*, Gabar Goshawk *Micronisus gabar*, Lanner Falcon *Falco biarmicus*, Peregrine Falcon *F. peregrinus*, Eurasian Hobby *F. subbuteo*, Black Kite *Milvus migrans* and Wahlberg's Eagle *Aquila wahlbergi* (see bat species profiles). Owls known to feed on African bats include Spotted Eagle-owl *Bubo africanus*, Mackinder's Eagle-owl *B. capensis mackinderi*, Giant Eagle-owl *B. lacteus* and Barn Owl *Tyto alba*. Silvery-cheeked Hornbills *Bycanistes brevis* prey on small fruit bats, which are attacked at their day-roosts (Kingdon 1973). However, because bats fly at night and usually roost in inaccessible places, predation is assumed to play a very minor role in bat mortality (e.g. Speakman 1995).

Bats are parasitized by a wide variety of internal parasites, including protozoans (e.g. *Plasmodium*), and worms in the classes Trematoda, Cestoda and Nematoda (for a catalogue of endoparasites of African bats, see Anciaux de Faveaux 1984). Bats are also parasitized by a wide variety of ectoparasites (Figure 31) including some families of arthropods that exclusively or almost exclusively parasitize bats (Marshall 1982, Hill & Smith 1984). However, bats are seldom heavily infested, they are unlikely to infest human dwellings with dangerous parasites, and bat parasites are not known to play a significant role in transmission of diseases to humans although some have the potential to do so. African bats, like other mammals, are parasitized by blood-sucking insects such as mosquitoes, midges and assassin bugs, which land briefly on the host, bite and then move elsewhere (for catalogue, see Anciaux de Faveaux 1984). Ectoparasites of African bats also include bed-bugs (order Hemiptera, family Cimicidae), which are blood-sucking insects that live in the day-roosts of bats and other mammals and move temporarily on to their hosts to feed, and their blood-sucking allies (Polycstenidae), which live permanently in the fur of bats and are not known to parasitize other animals. There are also blood-sucking fleas (order Siphonaptera) in the families Pulicidae (which parasitize a variety of mammals) and

Figure 31. Two commonly seen bat-flies of the order Diptera that are ectoparasites of African bats. (a) *Cylopodia greeffi* (Nycteribiidae), an ectoparasite of the fruit-bat *Eidolon helvum* (based on Happold 1987). (b) A winged bat-fly (Streblidae) (redrawn from Hill & Smith 1984).

Ischnopsyllidae (which parasitize bats only), and bat-flies (order Diptera, families Nycteribiidae and Streblidae) which parasitize only bats. Nycteribiids, which are wingless, can be seen scuttling through the pelage. Streblids of both sexes are winged, but the ♀♀ burrow into the skin (usually behind the ears), shed their wings and legs, and then develop into large, flask-shaped sacs with only the hind-parts exposed. Other Arthropods that parasitize African bats belong to the order Acari, and include ticks (families Argasidae and Ixodidae), which move temporarily on to bats (or other animals) to suck blood, and mites belonging to 16 families including the Spinturnicidae, which only parasitize bats. Some

mites live permanently on their hosts whereas others spend only part of their life-cycle on the bat host. Most mites feed on skin and skin products such as dead cells, hairs and secretions, and most mites live on specific sites on the host. For example, mites in the families Dermanyssidae, Laelapidae, Spinturnicidae, Cheyletidae and some species in the family Macronyssidae live on the skin, particularly in the ears, around the base of the tail, around the eyes, or on the wings. Mites in the family Erythetidae and some in the families Trombiculidae and Gastronyssidae live in the nasal passages. Some in the family Macronyssidae live in the mouth and feed on tissue between the teeth and gums, sometimes causing loss of teeth. Mites in the families Myobiidae and Chirodiscidae attach themselves to the hairs, and some in the family Gastronyssidae live on the corneae of the eyes. Mites in the family Sarcoptidae burrow into the skin and cause mange and scabies. Ectoparasites likely to be observed on African bats are listed in each species profile; the data are taken mainly from the catalogue compiled by Anciaux de Faveaux (1984), although since then there have been some changes in the names of both the ectoparasites and their hosts, and some of the hosts have been re-identified. Ectoparasites can be collected from both living and freshly killed bats, and are easily found by examining the bat under a 10–70 power zoom dissecting microscope. More information about collecting, preserving and studying ectoparasites of bats is given by Whitaker (1988).

The diseases of bats are poorly known. Anciaux de Faveaux (1984) catalogues bacteria, fungi and viruses that have been found in African bats but (with very few exceptions) they are not mentioned in the species profiles unless they are known to cause illness in humans and/or domestic livestock. A fungal disease of both bats and humans is histoplasmosis, a respiratory disease caused by inhaling the spores of *Histoplasma capsulatum* and *H. duboisii*, fungi that grow in soils with high content of organic matter including bat guano (Hill & Smith 1984). Histoplasmosis can be fatal to humans, although serious infections are rare: therefore people entering guano-rich roosts of bats should wear masks and, if possible, avoid disturbing the guano. Other fungi from guano in bat caves include *Microsporum gypseum* and *Trichophyton mentagrophytes* (which cause ringworm in humans and livestock). Viruses that have been isolated from African bats and that are known to cause fevers and more serious illnesses in humans include Bangui, Bunyamwera group, Chikungunya, Rift Valley Fever, Sindbis, West Nile, Yellow Fever and Zika viruses. These are arboviruses (transmitted by mosquitoes and/or other blood-feeding arthropods). Rift Valley fever and West Nile viruses infect both humans and livestock, Rift Valley fever being of particular importance in Africa. In addition, African bats have been shown to be infected with three rabies virus-like lyssaviruses, which can be transmitted to humans, via bites or scratches, when saliva from infected animals contacts exposed tissue and nerve endings. These are Duvenhage virus (which causes a rabies-like illness and has caused the death of at least one human), Mokola virus (also known to cause fatal human infections) and Lagos bat virus. Rabies virus has rarely been reported in African bats, although it occurs in some other African mammals. Other viruses that have been found in African bats, but are not known to cause illness in humans, include Bukalasa bat, Dakar bat, Entebbe bat, Fomede, Ife, Kasokero, Mt Suswa bat, Saboya, Uganda S and Yogue viruses. Of these, Uganda S virus is an arbovirus but the others, *contra* Anciaux de Faveaux (1984), are not

arboviruses (C. H. Calisher pers. comm.). In the aftermath of the 1995 Ebola haemorrhagic fever epidemic at Kikwit, DR Congo, 538 bat specimens (representing four families and 18 species) were collected at Kikwit in 1995 and examined for the presence of Ebola virus, but none was found in these bats (Van Cakenberghe *et al.* 1999). Recently, Ebola-viral RNA was detected in liver and spleen tissues of *Hypsignathus monstrosus*, *Epomops franqueti* and *Myonycteris torquata*, and Ebola virus-specific antibody was detected in the same species; however, Ebola-viral RNA was not detected in those with antibody, and antibody was not detected in those with Ebola-viral RNA (Leroy *et al.* 2005). It is not yet known whether the Ebola virus involved can be transmitted to humans, or whether it is pathogenic, and more studies are needed to determine whether these or other bats are susceptible to Ebola viruses and whether they play a role in Ebola-viral transmission (C. H. Calisher pers. comm.). Several of the viruses that can cause illness in humans have been isolated from unidentified species of bats, and therefore have not been mentioned in species profiles. These include Bangui virus from *Tadarida* sp., *Pipistrellus* sp. and *Scotophilus* sp. in Central African Republic; Chikungunya from *Scotophilus* sp., Duvenhage virus from *Miniopterus* sp., Sindbis from *Rhinolophus* sp. and *Hipposideros* sp., West Nile virus from *Rousettus* sp., *Scotophilus* sp. and *Tadarida* sp. and Zika virus from *Rousettus* sp. and *Tadarida* sp. Furthermore, viruses that have been isolated from Palaearctic bats have not been included in the profiles of these species. The fungi, ectoparasites and viruses mentioned above, and the diseases they cause, do not comprise a comprehensive record. They have been compiled from Anciaux de Faveaux (1984), Hill & Smith (1984), Calisher *et al.* (2006) and Internet sources, with additional information from P. Boland (pers. comm.). Since the profiles were submitted in 2006, there have been numerous publications about viruses found in African bats, but it was not possible to update the profiles.

Pests and benefactors

An extremely small percentage of the species of bats in Africa are justifiably considered pests. These include several species of very smelly molossids (e.g. *Tadarida pumila*, *T. condylura*), which roost in very large numbers in the roofs of houses, and a few species of fruit bats (e.g. *Hypsignathus monstrosus* and *Epomops franqueti*), which make very loud and monotonous calls at night. The vast majority of species are not only harmless to people, but are of great value. Many megabats play a major role in pollinating trees and dispersing their seeds and, although some have the reputation of raiding orchards, they almost always feed only on fully ripe fruits, which should have been picked earlier to be of commercial value (Baker & Harris 1957, 1959, Tuttle 1986). By removing over-ripe fruits, fruit bats may help to control fungal diseases and fruit-flies. Microbats are mainly insectivorous and their prey includes insects such as mosquitos, midges, flies and cotton-boll moths, which are very serious pests. Microbats, although seldom seen by humans, are very numerous and their impact on insect numbers is enormous. It was estimated that the 500,000 occupants of just one cave in Gabon consumed 3000 kg of insects each night within a radius of ca. 12 km (Brosset 1969). There are no blood-sucking vampire bats in Africa and there appear to be no records of humans being bitten by African bats unless the bats were captive and

being handled. Furthermore, the likelihood of someone contracting a disease as a result of being bitten by a captive bat that is being handled, or from a parasite of a bat, seems to be very low but not negligible (see Predators, Parasites and Diseases above).

Abundance

It is extremely difficult to determine the abundance of bats accurately. For most African species, there are no data. For others, it has only been possible to indicate comparative abundance, very roughly, from how often they are encountered and how well they are represented in collections. Even these estimations are of dubious value because bats are seldom encountered in countable numbers (except sometimes when their day-roosts are known) and, in most parts of Africa, methodical and comprehensive collecting and/or recording of bats has not been carried out. Also, the fact that a species is well represented in collections does not necessarily mean that it is comparatively abundant – it might just be easier to collect for one or more of several reasons. Species that roost in large numbers in accessible caves, mines and buildings may be collected from their roosts much more easily than those that roost singly or in small groups in inconspicuous roosts. Catching and/or detecting bats while they are flying around at night is very difficult and estimations of abundance based on these methods are unreliable. Although bats have been mist-netted and trapped close to the ground for some time, the setting of mist-nets and traps in and above the canopy is a recent and comparatively rare activity and, consequently, bats that fly in these environments are likely to be under-represented in collections. Furthermore, even the most sophisticated bat-traps and mist-nets only operate in a minute fraction of the space utilized by bats, and species that fly high (such as emballonurids, molossids and some vespertilionids) and species that are good at detecting and dodging mist-nets and traps (such as nycterids and *Kerivoula* spp.), are often poorly represented in surveys and collections. The ‘rarest’ of bats may well prove to be those that can avoid mist-nets and traps, those whose day-roosts are not known, those that live in areas where collecting effort has been minimal, and those whose echolocation calls are too low in intensity to be easily detected with bat-detectors.

Conservation

Two important assessments of the conservation status of bats that contain much relevant information are Mickleburgh *et al.* (1992), which is an action plan for the conservation of Old World fruit bats compiled by the IUCN/SSC Chiroptera Specialist Group, and Hutson *et al.* (2001), which is a global status survey and conservation action plan for microbats also compiled by the same organization. Since then, the conservation status (IUCN Categories) of many species have been updated from the Global Mammal Assessment Africa Workshop. The IUCN Categories (given in the species profiles) have been taken from the IUCN website (www.redlist.org). Additional information in species profiles is often taken from this website; some authors have also made their own comments. Although much effort has been given to the assessment of the conservation status of African bats, there are many species that are impossible to assess accurately,

either because they live in habitats that are rarely surveyed or because they are particularly difficult to capture.

Based on the 2010.4 version of the IUCN website, of the 224 species of bats in Africa, 14% are regarded as threatened to some extent: of these, five microbats (*Rhinolophus hilli*, *R. macclaudi*, *R. ziama*, *Hipposideros lamottei* and *Kerivoula africana*) are Endangered or Critically Endangered, two megabats and nine microbats are Vulnerable, and two megabats and 13 microbats are Near Threatened. There are 20 megabats and 124 microbats that are of Least Concern, and there are four megabats and 44 microbats referred to as 'Data Deficient' because their conservation status cannot be assessed from the available information. One new species has not yet been evaluated. The rapid increase in human population (and the concomitant increase in human activities that are detrimental to bats) is the single most serious threat to bat populations. Human activities that pose the greatest threats to bats in Africa include destruction of natural habitat, interference with day-roosts, hunting, and use of pesticides. In 1992, 18 species (64%) of the megabats were considered threatened by deforestation, and four (including the vulnerable *Pteropus voeltzkowi*) by hunting. The vast majority of microbats are threatened by destruction of natural habitats, reduction in abundance and diversity of insects, destruction of day-roosts in old and dead trees, disturbance of colonies in caves and old mines, and/or the use of pesticides. There are only ca. nine species that appear to thrive by roosting in human habitations and/or foraging over farmlands and gardens, and some of these are considered pests and their roosts are sometimes fumigated. Microbats are particularly susceptible to insecticides; they can be poisoned by eating contaminated insects, by contacting insecticides in buildings fumigated to eradicate insect pests, and they can be starved when insect numbers are reduced by insecticides. If the human population increases five-fold during the twenty-first century, as predicted by Bongaarts (1994), the outlook for most species of bats in Africa is bleak.

Chromosome numbers: a problem with terminology

The taxonomy sections of species profiles give information about chromosomes, if available to the authors of the profiles. This information includes the chromosome number (the usually constant number of chromosomes in a somatic cell of an organism): because chromosomes are paired, this number is referred to as $2n$. Some profiles also give the fundamental number. Fundamental number (FN) was originally defined as 'The number of chromosomal arms of the autosomal complement (excluding the sex pair) of a given species' (Matthey 1951). Subsequently, some authors included the sex chromosomes in their assessment of FN, and this made the term FN ambiguous. To avoid ambiguity, some authors then used 'aFN' to specify that only the arms of autosomal chromosomes were counted. Others continued to use FN, but specified whether or not the count was restricted to the autosomal chromosomes. Some used FN without specifying which chromosomes were included. For all profiles in the Order Chiroptera, it has been ascertained that only autosomal chromosomes were included, and therefore the number of arms is given as aFN whether or not this term was used in the cited source of the information.

Chiropteran origins, systematics and the families of African bats

Based on fossils and molecular evidence, bats are thought to have evolved from an ancestor living ca. 64 mya, and it seems that they diversified into four major microbat lineages (among which the megabats are nested) in the early Eocene, 50–52 mya (Teeling *et al.* 2005). At this time, mean annual global temperatures had increased by ca. 7°C, land plants were increasing in diversity and abundance, and insects were at the peak of their Tertiary diversity; consequently it is probable that the diverse echolocation and foraging strategies exemplified by microbats resulted from differential niche exploitation at this time. Teeling *et al.* (2005) suggest that bats originated in Laurasia (possibly in North America) and that, of the four major microbat lineages, three were Laurasian in origin and the fourth Gondwanan. The extant African bat fauna contains representatives of the three Laurasian lineages; the Gondwanan lineage is represented only by South American microbats.

The closest relatives of bats appear to be colugos (order Dermoptera) and, to a lesser degree, tree-shrews (order Scandentia) and primates (order Primates). Colugos are gliding lemur-like mammals with a large membrane extending from the fingers to the toes and to the tip of the long tail, and webbing between the fingers. Until 1970, it was assumed that all bats were monophyletic and that their common ancestor was the first flying mammal. Then it was suggested that self-powered flight evolved twice – in an ancestral megabat related to the primates, and in an ancestral microbat related to a small terrestrial insectivore (Jones & Genoways 1970, Smith & Madkour 1980, Pettigrew 1986, 1991). Although the morphological differences between megabats and microbats are substantial, and there are similarities (particularly in the nervous system) between megabats and primates, there is now convincing evidence that the order Chiroptera is monophyletic, and the 'diphyly controversy' has waned (Simmons 1994, 1995, Volleth *et al.* 2002, Teeling *et al.* 2005).

The higher-level classification of bats is controversial. Prior to the late 1900s, the megabats and microbats were placed in two suborders – the Megachiroptera and Microchiroptera, respectively. These taxa were supported by phylogenetic analyses based on morphological data (reviewed by Simmons & Geisler 1998), and both were considered to be monophyletic. However, phylogenetic studies based on different sets of data, and especially molecular evidence, strongly suggest that the suborder Microchiroptera is not monophyletic (Simmons 2005, Teeling *et al.* 2005); more details are given below. Therefore, following Simmons (2005) and pending further studies, the suborders Megachiroptera and Microchiroptera are not recognized here but, for convenience, the terms megabat and microbat are used when it is useful to distinguish between the fruit bats (family Pteropodidae) and the bats belonging to all other families. The main morphological differences between megabats and microbats are as follows:

Megabats (fruit bats). The membrane between the second and third fingers is more extensive than in microbats and these two fingers have some independence of movement. Both the thumb and the second finger have a claw. The muzzle is simple and there are no noseleaves (although in ♂♂ of *Hypsignathus*, the muzzle ends in a flat fleshy

plate). The ears are simple and well separated; the margin of each ear forms a complete ring around the auditory orifice. The eyes are very large and orientation is primarily by eyesight (not by echolocation). In all African megabats, the tail is short or absent; the interfemoral membrane is merely a flange of skin around the inner margins of the legs. The skull has a well-developed postorbital processes, and the bony palate extends well beyond the last molars (except *Casinycteris*). The molars are simple in all African genera (except, to some extent, *Hypsignathus*) and are without W-shaped patterns of cusps. There is only one family, the Pteropodidae, with 42 extant genera and 186 species worldwide (Simmons 2005).

Microbats. The second finger is closely associated with the third, and only the thumb has a claw. The muzzle may be simple or adorned by fleshy outgrowths (noseleaves). The external ear is often complicated; the margin does not form a complete ring, and a tragus is usually present. The eyes are small to very small and orientation is primarily by echolocation, not eyesight. The tail is usually long and fully or partly enclosed by a large interfemoral membrane, which stretches from heel to heel (but in one family, the tail is absent). The postorbital processes of the skull are usually absent, rudimentary or concealed (except in the Emballonuridae). The bony palate does not extend beyond the last molars. The molars have a W-shaped pattern of cusps

(albeit reduced in some species). There are 17 extant families, 160 extant genera and 930 species worldwide (Simmons 2005).

This usage of the terms megabat and microbat is not meant to be taken as support for the monophyly of these two groups. Indeed, recent evidence (summarized by Simmons 2005) suggests that the Microchiroptera are not monophyletic, and that microbats in the families Rhinolophidae, Hipposideridae, Megadermatidae, Rhinopomatidae (and the non-African family Craseonycteridae) are more closely related to megabats than to other microbats, including those in the African families Emballonuridae, Nycteridae, Molossidae and Vespertilionidae. This raises an interesting question – did laryngeal echolocation evolve more than once in bats, or did it evolve only once then become lost in megabats? This is only one of many unresolved problems associated with the relationships between the families of bats and, for this reason, following Simmons (2005), no taxa above the level of family are included here. On the other hand, again following Simmons (2005), the families are presented in the sequence that is consistent with the most recent classifications (see list above), and some interfamilial relationships are mentioned in each family profile.

In Africa, there are nine families. They are distinguished mainly by their heads (noseleaves, ears, tragus), and their tails and interfemoral membranes (Table 10, Figures 32 and 33).

Table 10. Key to the African families in the order Chiroptera. Data pertain to African representatives only. Ear lengths are relative and derived from mean E as percentage of mean FA for all species within each family: very short (22–37%), short (38–52%), medium (52–67%), long (68–82%), very long (83–97%).

| Second finger | Noseleaf | Tail and interfemoral membrane | Ears | Family |
|-----------------------|--|--|---|------------------------------|
| Terminating with claw | None | Tail absent or rudimentary. Interfemoral membrane reduced to narrow band along inside margin of hindlimbs | Very short; well separated; margin of ear uniquely forming a complete ring. No tragus | Pteropodidae (14 genera) |
| Without claw | None | Tail more or less completely enclosed by interfemoral membrane | Very short to very long; widely separated or joined. Tragus conspicuous | Vespertilionidae (17 genera) |
| Without claw | None | Terminal portion of tail projecting upwards through centre of interfemoral membrane when bats are not flying | Very short; widely separated, backward-pointing. Tragus conspicuous | Emballonuridae (3 genera) |
| Without claw | None | Terminal portion of tail projecting freely well beyond hind-margin of interfemoral membrane when bats are not flying; length of 'free' portion ca. half width of interfemoral membrane | Short; inner margins widely separated or meeting or joined by band of skin. Tragus inconspicuous | Molossidae (6 genera) |
| Without claw | Rudimentary, rounded | Tail extremely long; most of tail projecting freely beyond interfemoral membrane; 'free' portion very much longer than width of interfemoral membrane | Short; inner margins joined by band of skin across forehead. Tragus conspicuous | Rhinopomatidae (1 genus) |
| Without claw | Longitudinal slit bordered by fleshy outgrowths | Tail completely enclosed by interfemoral membrane; last vertebra T-shaped or Y-shaped | Medium to long; inner margins joined by inconspicuous low band of skin across forehead. Tragus conspicuous, not bifid | Nycteridae (1 genus) |
| Without claw | Very large; comparatively simple | Tail absent; interfemoral membrane very large | Long; inner margins joined for at least one-third of length. Tragus very conspicuous, bifid | Megadermatidae (2 genera) |
| Without claw | Very large; posterior component subtriangular with erect tip | Tail more or less completely enclosed by interfemoral membrane | Short to medium; well separated. No tragus | Rhinolophidae (1 genus) |
| Without claw | Very large; posterior component elliptical or with three pointed projections | Tail completely enclosed by interfemoral membrane or projecting slightly beyond it | Very short to medium; well separated. Tragus inconspicuous | Hipposideridae (4 genera) |

Figure 32. Heads of bats in the nine families represented in Africa. Update

Since this profile and all others were submitted in 2006, there have been many new publications (many referred to in *African Bat Conservation News*; www.Africanbats.org) but it was not usually possible to rewrite profiles or tables. However, sentences have been added to draw attention to new publications that substantially contribute to the taxonomy and distributions of African bats, and the

IUCN Categories of all species have been updated. Other sections of species profiles have not been updated. A very important publication – Monadjem *et al.* 2010 – contains some new information and references about the bats of southern and central Africa, and it contains photographs of skulls and living bats.

Meredith Happold

Family PTEROPODIDAE

FRUIT BATS (OLD WORLD FRUIT BATS)

The family Pteropodidae currently contains 42 extant genera and 186 species of which 14 genera and 28 species are found in Africa (Simmons 2005); some of the 28 species are considered to contain more than one species by some authors (see profiles). Traditionally, the pteropodids were placed in the suborder Megachiroptera (but see order Chiroptera). Consequently, they are often referred to as megabats but, in Africa, pteropodids are usually referred to, collectively, as fruit bats. Fruit bats have dog-like faces with very large eyes, well-separated erect ears and no noseleaf (Figure 32a); the tail is short or absent and the interfemoral membrane is merely a flange of skin around the inner margins of the legs (Figure 33a). There is a claw on the thumb and also at the end of the second finger (Figure 34a). All fruit bats feed on fruits and/or flowers or products of flowers and, in Africa, they are the only bats known to feed on plant products. Fruit bats are delightful animals. If handled gently, and encouraged with a mouthful of banana, they quickly lose their fear of people and it becomes obvious that they are very intelligent, very adaptable and curious enough to apparently enjoy new experiences as long as they bring comfort and nice things to eat! A few are regarded as pests when they raid orchards. However, although they may damage some fruits by biting to test ripeness, they only eat fruit that is too ripe for commercial value and, by removing this over-ripe fruit, they may help to control fungal disease and fruit-flies (Tuttle 1986). Fruit bats also play a vital role in the pollination of many trees including some which are not pollinated in any other way (Baker & Harris 1957, 1959, Harris & Baker 1959). They also play a vital role in the dispersal of the seeds of fruit-bearing trees (Thomas 1987, 1991). Bat-pollinated flowers are often large and robust, located at the edge of the foliage, and they only open and smell strongly during the night.

African fruit bats range in size from very small (FA: 38–62 mm) to very large (FA: 138–163 mm). In the larger species, ♂♂ are usually larger, on average, than ♀♀; however, the differences diminish with decrease in overall size and, in the very small *Nanonycteris*, the ♀♀ are larger, on average, than the ♂♂ (Bergmans 1989). Males often have secondary sexual characters (Figure 34). The pelage is typically of medium length and soft; the colour is usually uniformly fawn, grey, or brown, but some species have dark dorsal pelage and a contrasting bright red or yellow mantle across the neck and shoulders, and some

species have white markings (patches of white pelage) on the head that are of diagnostic importance. These markings include a white patch on the rostrum, a white spot behind each eye, white or whitish basal ear-patches and white upper lips (Figure 34). The basal ear-patches are often referred to as basal ear-tufts, however they are not strictly tufts but white hairs lining the basal parts of the margin of the ear. The body is elongated and robust; the head somewhat dog-like with short to very long muzzle and no noseleaf. The ears are well separated and simple; the bases of inner and outer margins join to form a complete ring around the auditory orifice; there is no tragus and no defined antitragus (Figure 34). The eyes are very large and are specially adapted to improve vision at night, as is typical of nocturnal mammals that do not echolocate. Although members of one genus (or perhaps two genera) have primitive echolocation, the majority of fruit bats cannot echolocate. The lips and cheeks of fruit-eating species are often wrinkled and expansible (i.e. able to stretch to form cheek-pouches in which large amounts of fruit can be carried). The tongue is either long, without backward-pointing hair-like papillae and with or without an expanded tip (fruit-eating species), or long with some hair-like papillae at the tip (*Plerotes*: diet uncertain), or very long with a brush of long hair-like papillae at the tip (nectar-eating species) (Figure 35). The tongues of fruit bats also have conical papillae for tasting food, and those of many (if not all) species also have a patch of tridentate papillae, stiff enough to serve as a rasp, fairly close to the tip. The soft palate has ridges forming patterns of diagnostic importance (Figure 34). The patterns include well-defined, conspicuous ridges, which are either thick or thin, interdental (between the rows of teeth) or postdental (further back than the last molars), and divided (if there is a median gap or groove across the centre) or undivided. Typically, there is a series of 3–12 of these conspicuous ridges beginning at the front of the palate, with a series of thin, flat, serrated ridges further back. Only the conspicuous ridges are of diagnostic importance. The wings of fruit bats are typically moderately short and broad. The thumb is usually long with a long claw, and the second finger has a metacarpal, two phalanges and a small claw. The wing-membrane on each side is usually attached (= inserted) to the first (= outer) toe or to the second toe; sometimes it is attached between these toes and, in some *Megaloglossus woermanni*, it is attached to the third toe (Figure 36). The hindlimbs are slender and moderately long; the toes are very long with long, sharp, curved claws, and all toes (except the first [= hallux]) have three phalanges. The tail is either short, vestigial or absent. The interfemoral membrane is poorly developed; typically, short calcars are present. There are no pubic nipples. Secondary sexual characters of adult ♂♂ include epaulettes, ruffs, mantles, which are more rigid and greasy than those of ♀♀, and (especially in *Hypsignathus*) various modifications of the head, skull and larynx associated with the production of loud vocalizations. An epaulette is a tuft of long white or yellowish hairs on each shoulder, which can be hidden within a deep pouch or displayed during courtship as a conspicuous circular whorl. It is often suggested that glands in the epaulette-pouches secrete scent, which is dispersed by the beating of the wings during courtship, but Püscher (1972) found fewer glands in the pouch than in normal skin, and concluded that

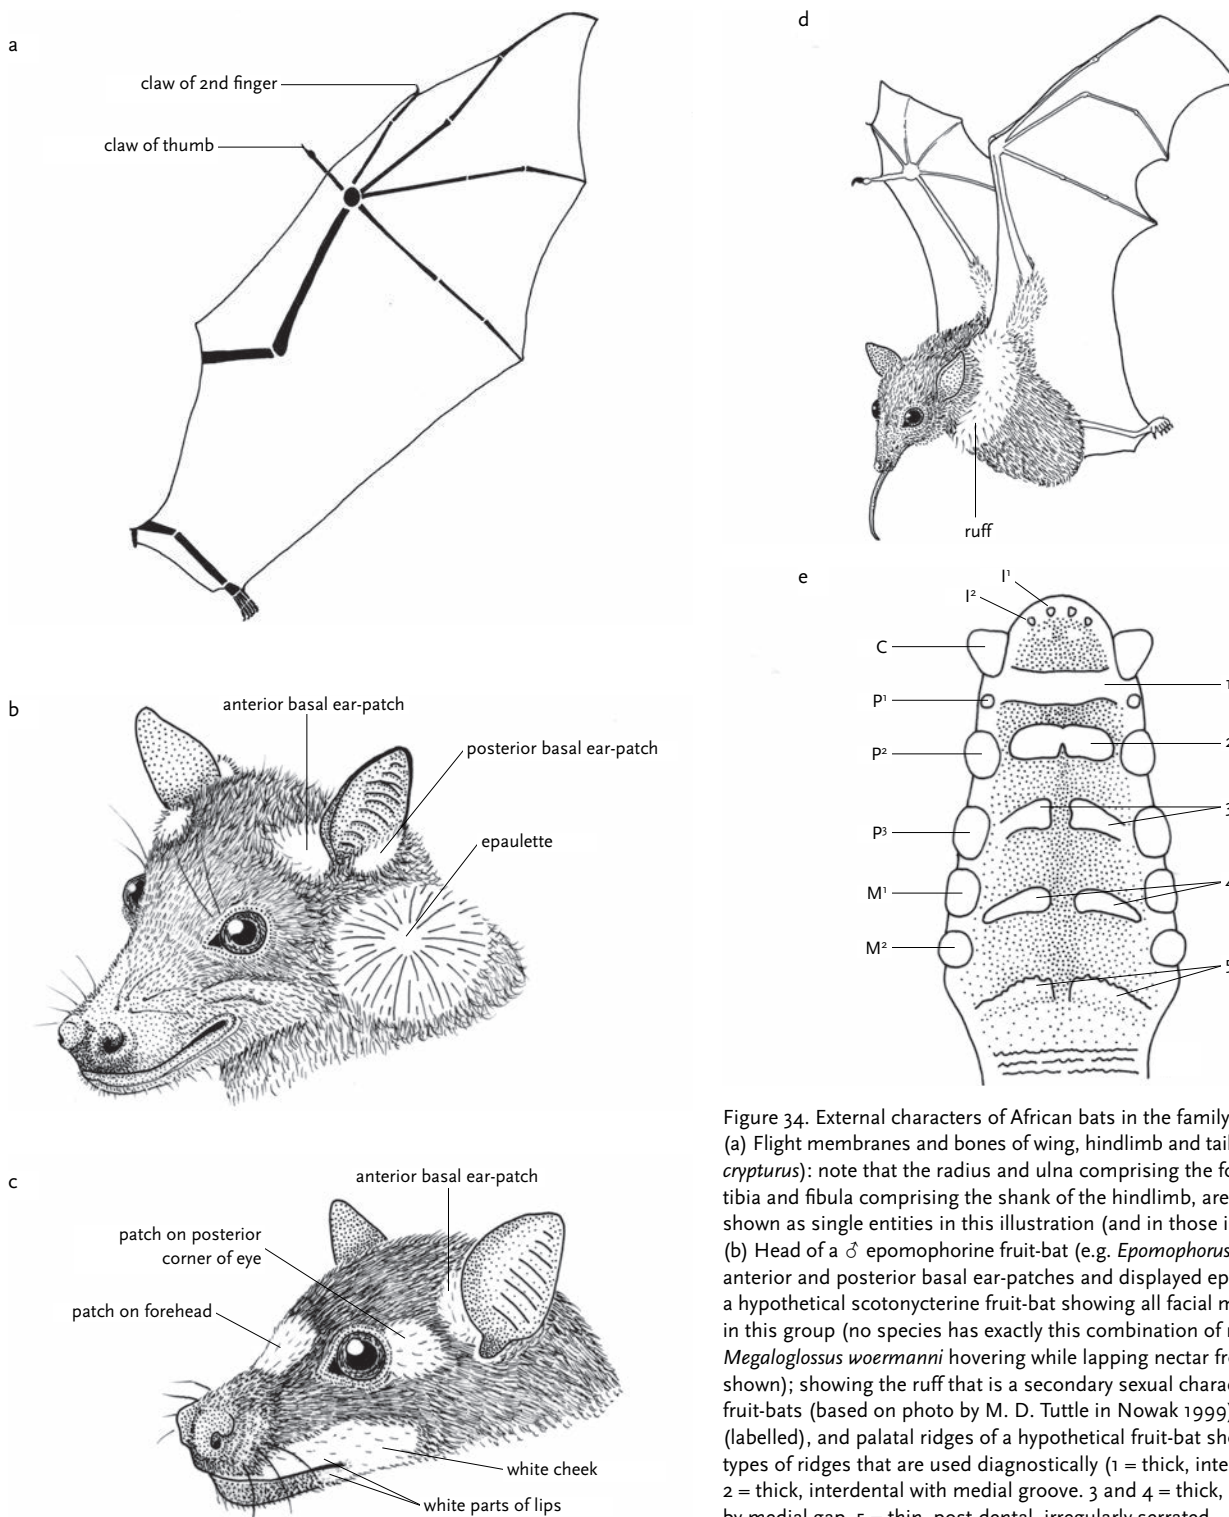

Figure 34. External characters of African bats in the family Pteropodidae. (a) Flight membranes and bones of wing, hindlimb and tail (e.g. *Epomophorus crypturus*): note that the radius and ulna comprising the forearm, and the tibia and fibula comprising the shank of the hindlimb, are fused and therefore shown as single entities in this illustration (and in those in other profiles). (b) Head of a ♂ epomophorine fruit-bat (e.g. *Epomophorus wahlbergi*) showing anterior and posterior basal ear-patches and displayed epaulette. (c) Head of a hypothetical scotonycterine fruit-bat showing all facial markings occurring in this group (no species has exactly this combination of markings). (d) Male *Megaloglossus woermanni* hovering while lapping nectar from a flower (not shown); showing the ruff that is a secondary sexual character of myonycterine fruit-bats (based on photo by M. D. Tuttle in Nowak 1999). (e) Upper teeth (labelled), and palatal ridges of a hypothetical fruit-bat showing the main types of ridges that are used diagnostically (1 = thick, interdental, not divided. 2 = thick, interdental with medial groove. 3 and 4 = thick, interdental, divided by medial gap. 5 = thin, post-dental, irregularly serrated).

epaulettes make purely visual signals. The possibility that wing-beating wafts scents bearing olfactory signals from other parts of the body invites investigation. A ruff (or collar) is a wide band of hairs that differ in colour, length and/or texture, extending from the shoulders across the throat and upper chest; in some species, ruffs arise from glandular skin and are stained by glandular secretions.

The skulls of fruit bats are easily distinguished from the skulls of microbats. The rostrum can be short to very long, tapering or (in

Hypsignathus) domed and square-ended. Postorbital processes are well developed and slender, and they curve outwards and downwards behind the orbit (as in Emballonuridae). There are no supraorbital ridges; the sagittal crest is low or absent, the lambdoid crest is very low or absent and there is no occipital helmet. The premaxillae have only the nasal branches present; the palatal branches are absent leaving a deep-wide anterior palatal 'emargination', which may, or may not, open anteriorly between the incisors. The bony palate extends

Figure 35. Characteristics of the papillae on tips of tongues of some fruit-bats. (a) *Hypsignathus monstrosus* (based on Lang & Chapin 1917b), (b) *Megaloglossus woermanni* (based on photo in Kulzer 1982) and (c) *Pterotes anchietae* (based on Harrison 1960). (d) anterior filiform papilla for collecting nectar. (e) Tridentate papilla, stiff enough to serve as a rasp. (f) Posterior hair-like papilla. Tongues not drawn to scale.

posteriorly well beyond the teeth (except in *Casinycteris*). The teeth are in an evolutionary process of becoming simpler (e.g. by losing cusps), smaller (especially the first premolars and posterior molars) and fewer. Dental formulae are usually $2^{121}/_{2132} = 28$ or $2^{132}/_{2133} = 34$. The teeth are well separated (cf. in close contact in microbats). The canines are long and curved; the molars are with or without cusps and the cusps are separated by smooth shallow troughs (cf. with a W-shaped pattern of sharp cusps in microbats [reduced in some species]). The dentition is highly specialized for crushing pulpy fruit.

Most African fruit bats for which data are available ($n = 8$) have low to very low aspect ratios (medium in *Micropteropus pusillus*), and medium to exceptionally high wing-loadings. Most can fly fast and direct in the open, or slowly with considerable manoeuvrability through branches and foliage. Most fly most of the time that they are

Figure 36. Left hindlimbs of three fruit-bats showing attachment of the wing to (a) the first toe (e.g. *Rousettus aegyptiacus*), (b) the second toe (e.g. *Myonycteris torquata*) and (c) the third toe as in some *Megaloglossus woermanni*. In some species, the wing is sometimes attached between the first and second toes.

airborne and only glide very short distances, but some flying-foxes (*Pteropus*) have become specialist gliders and soarers (Norberg *et al.* 2000). Some fruit bats can hover briefly and sometimes do so while collecting nectar or fruit. Some can take off from the ground, which enables them to feed on fallen fruit. Most species glide towards a perch and, at the last moment, stall, somersault and grasp the perch with their hindfeet. Others, such as some flying-foxes, fly slowly over a perch, grasp it with the hindfeet and then topple down into the hanging position. Many also make rather uncontrolled crash-landings on to foliage. Because they do not fly in pursuit of moving prey, they typically lack agility and do not perform aerial acrobatics (cf. microbats). Most African fruit bats eat the ripe soft-skinned fruits (sometimes also flowers) of rainforest, savanna and cultivated trees. Typically, they land onto fruit-bearing vegetation and use thumbs, wings and sometimes a foot, to manipulate the fruit so it can be bitten. The thumb can be opposed against the fingers, and the second finger has more mobility than in microbats; consequently the wing can be used somewhat like a hand. Whole fruits, or large pieces, are packed into the cheek-pouches and then carried to a perch where the bat hangs and slowly chews the fruit. To avoid carrying extraneous weight, only the energy-rich juice and small amounts of pulp are swallowed – the fibre and seeds are discarded. Juice is extracted by crushing the pulp between the teeth, sucking it and squeezing it against the palatal ridges. Fruits are a poor source of proteins and minerals: some fruit bats chew leaves and swallow the juices, presumably to obtain these nutrients. Furthermore, some flying-foxes fly off-shore apparently to drink seawater, possibly as a means of obtaining salts (Ratcliffe 1961, Bergmans 1978, Iudica & Bonaccorso 2003). The passage of food through the digestive tract is

very rapid (average 30 min) (Nowak 1999). The kidneys are adapted to excrete large volumes of very dilute urine, and to maximize the retention of salts and other solutes (Happold & Happold 1988). However, despite the large amount of water in the diet, several African fruit bats (*Eidolon helvum*, *Rousettus aegyptiacus*, *Hypsignathus monstrosus*) drink in captivity and, in the wild, *Eidolon helvum* and *Epomophorus gambianus* have been seen skimming over open water and making contact with the surface, but it is not yet certain that they do this to obtain water for drinking (Bergmans 1978). It is conceivable that *Eidolon helvum*, which dips its hindlimbs into the water, might be trawling for fish (Bergmans 1978). Some fruit bats, including *Megaloglossus woermanni* in Africa, are specialist nectar/pollen eaters that hover or land on flowers that are adapted for pollination by bats, and lap the nectar and/or pollen with their very long, brush-tipped tongues. Fruit bats locate food by smell, often at very long range; their olfactory lobes and sense of smell are highly developed (Möhres & Kulzer 1956). Fruit bats have colour-vision and, at close range, fruits are located by sight. Some fruit bats fly as much as 60 km between day-roost and feeding-ground, and then back again.

African fruit bats are dependent on trees for food and most are also dependent on trees for shelter. The abundance of fruit bats at many localities is determined by the seasonal availability of fruits and flowers; some species migrate and many are nomadic for this reason. Fruit bats are not adapted for cursorial locomotion such as scuttling, but some are fairly competent climbers; they swing along under thin branches, holding on with the claws of their thumbs and toes, and moving the wings in alternation. Some can also climb head-first up or down vertical surfaces. Some, if not all, can swim by using their wings as oars, but swimming is not a normal occurrence. During the day, most African fruit bats roost in trees or shrubs, hanging freely from thin branches, usually well concealed in the shade of foliage but sometimes in the open. Brownish pelage, white markings on the heads of many species, and pale skin over the wing-bones, probably contribute to the cryptic appearance of roosting fruit bats (Fenton 1992). Some fruit bats habitually roost in caves: *Rousettus* in dark caves, *Lissonycteris* in dimly lit caves. *Rousettus*, like all other fruit bats, perceive their surroundings by eyesight, even at night. However, at least three species also use a primitive form of echolocation (clicks made by the tongue) to find their way inside dark caves. Most roosting fruit bats temporally hang by their thumbs while urinating or defaecating. Fruit bats are mainly nocturnal, but some species leave their day-roosts at sunset and some in the late, or even early, afternoon. Some fruit bats roost singly, others in small to very large groups. Some are very noisy and restless during the day; others stay quiet and still. Fruit bats do not hibernate. Little is known about their social behaviour and mating systems with the exceptions of *Hypsignathus* (which has a classical lek mating system), *Epomops buettikoferi* and *E. franqueti* (which have exploded lek mating systems [sensu Bradbury 1981]) and *Pteropus seychellensis* (which appears to have a harem mating system of some sort). Some aspects of the social behaviour of *Epomophorus wahlbergi* and *Rousettus aegyptiacus* are also known although the mating systems of these species have not yet been elucidated. Males of some species attract mates by performing calling displays during which they make loud calls, beat their wings and display their epaulettes; they have a well-developed larynx and amplifying chambers.

Most fruit bats are monogamous (Hill & Smith 1984) but twinning has been reported in *Epomops dobsonii* (Hill & Smith 1984) and very

occasionally in *Eidolon helvum*, *Epomophorus wahlbergi*, *Megaloglossus woermanni*, *Nanonycteris veldkampii* and *Rousettus aegyptiacus*. Reproductive chronologies include restricted seasonal monoestry, extended seasonal monoestry, aseasonal monoestry, continuous bimodal polyoestry with postpartum oestrus, seasonal bimodal polyoestry without postpartum oestrus, perhaps aseasonal polyoestry and perhaps bimodal monoestry. One species, *Rousettus aegyptiacus*, exemplifies four of these chronologies at four different localities! Investigations of fruit bat reproductive chronologies are often hampered by the nomadic movements of the bats; there may be reliable evidence of births in one season but no data for other times when second births may be occurring elsewhere. *Eidolon helvum*, which has delayed implantation, is the only African fruit bat known to show any form of reproductive delay (Bernard & Cumming 1997). There appears to be a trend (exemplified intra-specifically by *Rousettus aegyptiacus* and *Epomophorus wahlbergi*) towards polyoestry in the tropics and monoestry at higher latitudes (Happold & Happold 1990a, Bernard & Cumming 1997, and species profiles). In the tropics, ten species are polyoestrous, four probably polyoestrous, one monoestrous, two probably monoestrous and there is no information for 11 species. In southern Africa, there are three monoestrous species (including the migratory *E. helvum*, which does not give birth in the region), and there is no information for one species. There is also evidence suggesting that some of the species in equatorial rainforests, peripheral savannas and/or woodland savannas north of the Equator, have inflexible chronologies that are, perhaps, better suited to some environments than others (Fayenuwo & Halstead 1974, Thomas & Marshall 1984, Happold & Happold 1990a).

Fruit bats are distributed mainly in forests and woodlands throughout the tropical and sub-tropical regions of the Old World (including islands in the Indian and Pacific oceans), wherever flowering and fruiting trees are present to provide food. They are not found in the New World, where the fruit and nectar-feeding niche is exploited by the Phyllostomidae, a family of microbats that is not represented elsewhere. Of the 28 species in Africa, 24 are found only in the tropics and sub-tropics, and four are mainly tropical but extend southwards into the temperate region of southern Africa. Eight species are found only or mainly in forests, nine in both forests and savannas, nine only or mainly in savannas and two only on islands. Eighteen species are found only on the mainland, eight mainland species also occur on Bioko I. and/or on at least one of the islands off the coast of East Africa (Pemba I., Zanzibar and Mafia I.), and two species are island specialists found only on Pemba I. or Mafia I. Only one species (*Rousettus lanosus*) is found mainly in montane habitats, but 13 species (48%) extend into montane habitats. Most localities suitable for fruit bats are probably exploited by more than one species; some localities have 4–10 species, for example:

Mt Nimba, Liberia (Rainforest and Montane Forest): *Eidolon helvum*, *Epomops buettikoferi*, *Hypsignathus monstrosus*, *Lissonycteris angolensis*, *Megaloglossus woermanni*, *Myonycteris torquata*, *Nanonycteris veldkampii*, *Rousettus aegyptiacus*, *Scotoonycteris ophiodon* and *S. zenkeri* (Coe 1975).
Luluabourg, DR Congo (Rainforest–Savanna Mosaic): *Casinycteris argynnis*, *Eidolon helvum*, *Epomophorus wahlbergi*, *Epomops franqueti*, *Hypsignathus monstrosus*, *Megaloglossus woermanni*, *Micropteropus intermedius* and *M. pusillus* (Hayman *et al.* 1966).
Zomba, Malawi (miombo woodland): *Eidolon helvum*, *Epomophorus crypturus*, *E. labiatus* and *E. wahlbergi* (Happold & Happold 1997).

The geological range of the Pteropodidae is early Miocene to Recent in Africa, Pleistocene to Recent in Madagascar and East Indies, and Recent in other parts of its geographic range (Koopman 1984, McKenna & Bell 1997); the early Oligocene *Archaeopteropus transiens* from Europe was removed from Pteropodidae by Schutt & Simmons (1998). There is also a late Eocene premolar from Thailand attributed to Pteropodidae, probably an epomophorine (Ducrocq *et al.* 1993), although some authors have not accepted the pteropodid affinities of this fossil (Teeling *et al.* 2005). A phylogeny based on DNA hybridization suggests that the Pteropodidae originated in the Australo-Pacific or South-East Asia at the end of the Cretaceous (Kirsch *et al.* 1995). An Australasian origin has been confirmed by Giannini & Simmons (2005). Collectively these results also suggest that, having initially specialized in eating mainly fruit (as opposed to insects), the pteropodids have diverged, repeatedly, towards eating either both fruit and nectar, or mainly flower products. For example, Giannini & Simmons (2005) demonstrated that specialist nectar-eating probably evolved at least three times in pteropodids. At the present time, there are ca. 37 fruit-eating genera and only six nectar-eating genera. Kirsch *et al.* (1995) suggest that the prevalence of fruit-eating pteropodids does not mean that fruit-eating is primitive, but Giannini & Simmons (2005) recovered specialized nectarivores nested within clades of frugivores, suggesting a primitively frugivorous feeding habit for pteropodids. Kirsch *et al.* (1995) also pointed out that the food preferences of pteropodids are not tightly correlated with anatomy, and they see this as further evidence that there have been repeated shifts between nectar-eating and fruit-eating in this family. In contrast, Giannini & Simmons (2005) reported fewer instances of parallel evolution of the nectarivorous habit and therefore lesser incongruence between anatomy and dietary habits. Other recent studies indicate that cave-dwelling has originated several times, and it is not yet known if echolocation has evolved only once in the Pteropodidae (as indicated by Giannini & Simmons 2003, 2005), or more than once (see Genus *Rousettus*). The number of times that Africa has been colonized by pteropodids is controversial. Kirsch *et al.* (1995), Springer *et al.* (1995) and Romagnoli & Springer (2000), for example, conclude that Africa has been invaded by one taxon that gave rise to all of the African genera (except possibly *Eidolon*, whose affinities are unclear); this has been referred to as the endemic-African-clade hypothesis (e.g. by Giannini & Simmons 2003). In contrast, Juste *et al.* (1999) suggest that at least three colonization events have occurred, the first (probably in the Miocene via forested corridors linking African and Asian rainforests) associated with the diversification that gave rise to most of the extant African fruit bats including *Rousettus* (*Stenonycteris*) *lanosa* (as *Stenonycteris*), a more recent event for the African *Rousettus* (from which they exclude *Stenonycteris*), and a third associated with *Eidolon*. Giannini & Simmons (2003) suggest an even more complicated scenario in which fruit bats colonized Africa at least four independent times; they indicate that *Stenonycteris* nests among Indomalayan species, which suggests that it is not a member of an African clade and that its occurrence in Africa must have been associated with a separate colonization event, and also that the colonization of islands in the western Indian Ocean and off the East African coast by *Pteropus* should also be counted as one or more separate colonization events (see Genus *Pteropus*).

With all this in mind, it is not surprising that the systematics of the Pteropodidae is controversial. On the basis of morphological

characters, Andersen (1912a) divided the pteropodids into three subfamilies – the Macroglossinae (containing all of the specialized nectar-feeding pteropodids including the African genus *Megaloglossus*), the Pteropodinae (containing most other pteropodids including all of the other African genera) and the Harpyionycterinae (containing one aberrant genus, which does not occur in Africa). Andersen (1912a) also divided the Pteropodinae into five ‘sections’ – the Eonycterine, Notopterine, *Epomophorus*, *Cynopterus* and *Rousettus* sections. Andersen’s *Epomophorus* section contained the African genera *Epomophorus*, *Hypsignathus*, *Epomops*, *Micropteropus*, *Casinycteris*, *Scotonycteris*, *Plerotes* and *Nanonycteris* – a group often referred to as the epomophorine fruit bats. Many of Andersen’s conclusions were supported by the results of subsequent studies, but some were challenged (e.g. Haiduk *et al.* 1983, Bergmans 1988, 1989, 1990, Kirsch *et al.* 1995, Springer *et al.* 1995, Juste *et al.* 1997) and, based on these studies and other work of his own, Bergmans (1997) tentatively proposed a new classification of the Recent Megachiroptera in which the African genera were placed into the following subfamilies and tribes:

Subfamily Rousettinae:

Tribe Rousettini: *Rousettus*, *Eidolon*

Subfamily Pteropodinae

Tribe Pteropodini: *Pteropus*

Subfamily Epomophorinae

Tribe Epomophorini: *Epomophorus*, *Epomops*, *Hypsignathus*, *Micropteropus*, *Nanonycteris*

Tribe Myonycterini: *Lissonycteris*, *Megaloglossus*, *Myonycteris*

Tribe Scotonycterini: *Casinycteris*, *Scotonycteris*

Tribe Plerotini: *Plerotes*.

Some phylogenetic studies based on molecular characters have indicated that (a) high levels of homoplasy have resulted in misleading taxonomic arrangements based on morphological characters, (b) the Epomophorinae *sensu* Bergmans is perhaps not monophyletic, (c) there is support for a large clade of endemic African taxa including genera previously placed in several different subfamilies or tribes and (d) the position of *Eidolon* is not clear (Hollar & Springer 1997, Álvarez *et al.* 1999, Romagnoli & Springer 2000, Giannini & Simmons 2003 and others [see Simmons 2005]). However, the most recent phylogenetic analyses (Giannini & Simmons, 2005) have suggested that Bergmans’s (1997) classification is largely corroborated with regard to the African taxa, with the exception of the placement of *Eidolon*, which does not belong in the Rousettinae and may instead be a member of a pteropodine clade. However, the relationships between pteropodid genera are not yet fully resolved and therefore, pending a re-evaluation of pteropodid classification, Simmons (2005) does not recognize any subfamilial or tribal groups. Likewise no subfamilial or tribal groups are included here.

The 14 genera of fruit bats in Africa are distinguished by size and the various characters given in Table 11. Following Simmons (2005), the genera of fruit bats, and the species within each genus, are presented in alphabetical order.

Table 11. Key to the African genera in the family Pteropodidae. The number of cheekteeth very occasionally varies from the usual numbers given below; for details, see genus profiles.

| Tongue brush-tipped | White or whitish markings on head | Epaulettes on shoulders of adult ♂♂ | FA range (mm) | Muzzle | Cheek-teeth (upper/lower) | Miscellaneous | Genus |
|---------------------|--|-------------------------------------|--------------------|---------------------------------|--|---|----------------------|
| Yes | None | Absent | 38–49 | Elongated | $\frac{5}{6}$ | Toes not webbed or very weakly webbed
Adult ♂♂ have ruffs | <i>Megaloglossus</i> |
| Moderately | No white markings on face
Basal ear-patches present (sometimes inconspicuous) | Absent | 47–53 | Simple | $\frac{4}{6}$ or $\frac{4}{5}$
or $\frac{5}{6}$ | Interfemoral membrane reduced to very narrow flange along legs
Calcars absent | <i>Plerotes</i> |
| No | None | Absent | 145–163 | Simple | $\frac{5}{6}$ | Red or yellow mantle present
Not on mainland Africa | <i>Pteropus</i> |
| No | None | Absent | 105–135 | Simple | $\frac{5}{6}$ | No mantle
Present on mainland Africa and some offshore islands | <i>Eidolon</i> |
| No | None | Absent | 82–106 | Simple | $\frac{5}{6}$ | Toes not webbed
Echolocates
M ² not greatly reduced
Ruffs absent | <i>Rousettus</i> |
| No | None | Absent | 68–90 | Simple | $\frac{5}{6}$ | Toes partly webbed
No echolocation
M ² not greatly reduced
Adult ♂♂ have ruffs | <i>Lissonycteris</i> |
| No | None | Absent | 56–75 | Simple | $\frac{5}{6}$ or $\frac{5}{5}$ | Toes not webbed
No echolocation
M ² greatly reduced
Adult ♂♂ have ruffs | <i>Myonycteris</i> |
| No | White markings on face
Basal ear-patches inconspicuous or absent | Absent | 47–87 ^a | Simple | $\frac{3}{5}$ | Bony palate extending well beyond teeth
Rostrum (viewed laterally) not upturned | <i>Scotonycteris</i> |
| No | White markings on face
Basal ear-patches present (sometimes inconspicuous) | Absent | 50–62 | Simple | $\frac{3}{5}$ | No postdental bony palate
Rostrum (viewed laterally) slightly upturned | <i>Casinycteris</i> |
| No | No white markings on face
Basal ear-patches present (sometimes inconspicuous) | Absent | 112–139 | Truncated; ends in fleshy plate | $\frac{3}{5}$ | | <i>Hypsignathus</i> |
| No | No white markings on face
Basal ear-patches present | Present | 54–100 | Simple | $\frac{3}{5}$ | Interfemoral membrane wide
Calcars present
6 thick palatal ridges | <i>Epomophorus</i> |
| No | No white markings on face
Basal ear-patches present | Present | 77–102 | Simple | $\frac{3}{5}$ | Interfemoral membrane wide
Calcars present
3 or 5 thick palatal ridges | <i>Epomops</i> |
| No | No white markings on face
Basal ear-patches present | Present | 46–64 | Simple | $\frac{3}{5}$ | Interfemoral membrane wide
Calcars present
5–6 palatal ridges; all divided except first
C–M ¹ : 8.0–ca. 10.6 mm | <i>Micropteropus</i> |
| No | No white markings on face
Basal ear-patches present | Present | 46–54 | Simple | $\frac{3}{5}$ | Interfemoral membrane wide
Calcars present
12–13 palatal ridges; posterior group of 8–9 narrowly divided
C–M ¹ : 6.8–7.7 mm | <i>Nanonycteris</i> |

^a Includes specimens from Congo, which are larger than those from elsewhere (see genus profile).

GENUS *Casinycteris*

Short-palated Fruit Bat

Casinycteris Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 6: 111. Type species: *Casinycteris argynnis* Thomas, 1893.

Casinycteris argynnis.

This monotypic genus is endemic to Africa and found only in the Rainforest BZ and Rainforest–Savanna Mosaic in S Cameroon, Central African Republic and DR Congo. Diagnostic characters: white markings on the nose, upper lips and near the eyes; white basal ear-patches (sometimes inconspicuous); adult ♂♂ without epaulettes; FA: 50–62 mm; practically no bony palate posterior to the teeth; rostrum (viewed laterally) slightly upturned; canines long; three upper and five lower cheekteeth. Similar to *Scotonycteris* but see Table 11, p. 228. The palatal ridges and craniodental characters of *Casinycteris argynnis* are illustrated in Figure 37.

Although many microbats are short-palated, no other African fruit bat has a reduced palate and it is assumed to be a derived character (Bergmans 1990). Morphologically, *Casinycteris* closely resembles *Scotonycteris*, with *S. ophiodon* being intermediate between *Casinycteris* and *S. zenkeri* (Bergmans 1990). It has been argued that the reduction of the palate might be a relatively simple genetic

Figure 37. *Casinycteris argynnis*. Palatal ridges (RMCA F 75-56-M-98; see Meirte 1983 for variations). Skull (RMCA 97-021-M-579, adult ♀).

change not important enough to serve as the basis of a genus (Pohle 1943), but Bergmans (1990) gives several other reasons for maintaining *Casinycteris* as a genus as opposed to a subgenus or synonym of *Scotonycteris*. These include the following differences. In

Casinycteris, the orientation of the foramen magnum is rather more horizontal than in *Scotonycteris*. In *Casinycteris*, the rostrum profile is slightly upturned (cf. not upturned in *Scotonycteris*), and there is a distinct angle between rostrum and braincase in the profile of the skull (viewed laterally) (cf. in *Scotonycteris* the border is not so sharply marked). In *Casinycteris*, the orbital cavity is relatively larger than in *Scotonycteris*, and the ears are relatively larger. Differences between *Casinycteris* and *S. zenkeri* are more marked: as well as the reduced palate, *Casinycteris* has a shorter rostrum, stronger and more widely spread zygomatic arches, more strongly developed postorbital and cranial ridges, and generally higher and more pointed teeth (Thomas 1910). These differences suggest that the diet and feeding behaviour of these two species are different (Lang & Chapin 1917b, Bergmans

1990) and that competition between these species, where they occur sympatrically, is reduced accordingly (Andersen 1912a).

Casinycteris is reviewed by Bergmans (1990). *Casinycteris* was placed in the *Epomophorus* section of Andersen (1912a). Subsequently, based on morphological characters, *Casinycteris* was placed (with *Scotonycteris*) in the subfamily Epomophorinae and tribe Scotonycterini by Bergmans (1997). The close relationship of *Casinycteris* and *Scotonycteris*, and the grouping of these genera with other genera in the *Epomophorini*, is supported by the phylogenetic analyses of Springer *et al.* (1995) and Romagnoli & Springer (2000).

The single species is *Casinycteris argynnis*.

Meredith Happold

Casinycteris argynnis SHORT-PALATED FRUIT BAT

Fr. Casinyctère dorée; Ger. Goldener Kurzgaumen-Flughund

Casinycteris argynnis Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 6: 111. Dja River, Bitye, Cameroon.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Very small, brown fruit bat with face-markings (white patch on forehead, white posterior eye-spots, partly white lips, white cheeks); whitish anterior basal ear-patches (sometimes indistinct); no epaulettes; snout and finger-joints yellowish; forehead region of skull strongly concave; bony palate uniquely shortened; FA: 50–64 mm. Males and ♀♀ similar in colour (juveniles probably darker); ♀♀ larger, on average, than ♂♂. Pelage woolly; extending dorsally and ventrally over upper arm and halfway along each forearm; mid-dorsal hairs 7–8 mm, shorter and sparser ventrally. Dorsal pelage medium brown (sepia to slightly russet); hairs beige with dark brown at base and medium brown at tip. Ventral pelage medium brown on flanks merging into paler brown on throat, neck and mid-ventrally. No epaulettes. Head brown with white patch on forehead, white patch at posterior corner of each eye, whitish anterior basal ear-patches (sometimes inconspicuous), white cheeks, white chin and white lips (posterior half only). No posterior basal ear-patch. Ears relatively long for a fruit bat (26–35% of FA), rounded. Ears, nostrils and lips with yellow or yellowish-brown pigmentation. Lips and cheeks fleshy and expansible. Palate with three or four thick and one thin serrated interdental ridges (the last of which is sometimes divided), and many crowded, irregular, thin and serrated postdental ridges (Figure 37). Wings brown with some parts orange-brown or yellowish-brown when alive, and with distinctly darker reticulation lines; wing-membranes attaching to first toe. Wing-bones dark except at joints, which are pale yellow or pale yellowish-brown. Thumbs long (ca. 26 mm). No visible tail.

Skull (Figure 37) short for an African fruit bat. Braincase strongly rounded; rostrum relatively short, slightly upturned. Profile of forehead region (viewed laterally) strongly concave (cf. *Scotonycteris*). Zygomatic width relatively great (71–79% of GLS); zygomatic arches comparatively strong with ventral margins almost at level of alveolar line (Bergmans 1990) (cf. *Scotonycteris*). Bony palate extremely reduced so there is practically no postdental palate (cf. all other African fruit bats), although soft palate continues as far back as in other fruit bats. For specimens with the soft palate

intact, the posterior margin of the bony palate can be felt with a blunt probe. Upper incisors comparatively short (cf. *Scotonycteris ophiodon*). Upper canines tall, markedly curved backwards (as in *Scotonycteris ophiodon*); inner edges usually smooth, sometimes with slightly serrated appearance when worn. Premolars and molars with well-developed inner cusps (especially P⁴, P₃ and P₄) (cf. *Scotonycteris zenkeri*). Dental formula $\frac{2121}{2132} = 28$.

Geographic Variation None known.

Similar Species Only two other African fruit bats have white markings on the forehead, upper lip and behind the eyes:

Scotonycteris ophiodon. Much larger (FA: 73–87 mm; GLS: >35 mm).

Forehead region of skull only weakly concave; rostrum not upturned; bony palate extending well beyond last teeth.

S. zenkeri. Forearm often shorter (47–55 mm). Finger-joints brown.

Forehead region of skull almost straight; rostrum not upturned; bony palate extending well beyond last teeth.

Distribution Endemic to Africa. Known from 17 localities in Rainforest BZ and Southern Rainforest–Savanna Mosaic, in S Cameroon, Central African Republic and DR Congo (Bergmans 1990, Lunde & Beresford 1997), but likely to occur more widely within these zones. More recently, in 2000 and 2003, ten specimens were collected from Mabira F. R. in C Uganda (00° 23' N, 33° 01' E) (Kityo *et al.* 2009): this locality, which extends the known range eastwards by ca. 500 km, is not mapped.

Habitat Wetter and drier types of lowland rainforest, disturbed secondary forest, mosaics of forest with secondary grassland, and riverine forests (Bergmans 1990, Van Cakenberghe *et al.* 1999). Also swamp forest where few other fruit bats have been found (Bergmans 1990).

Abundance Very rarely recorded, but perhaps locally abundant: several specimens were mist-netted on one day at one locality

*Casinycteris argyrenis*

(Meirte 1983); 14 caught in five weeks at Irangi, DR Congo (Bergmans 1990).

Remarks Aspect ratio very low; wing-loading medium ($n = 1$); flight predicted to be slow and manoeuvrable. One ♀ was found hanging singly in the dense foliage of a bush 3 m above the ground (Lang & Chapin 1917b). The yellowish colour and reticulation of the wings suggest reliance on camouflage while roosting in foliage. The uniquely reduced bony palate, and several other characters of the skull and dentition, suggest that the food and feeding behaviour might be different from that of most other fruit bats (Lang & Chapin 1917b).

Reproduction and Population Structure No conclusive data. Within three degrees of the Equator, two pregnant ♀♀ (one also lactating), one lactating ♀ and one immature ♀ were taken

in Jan–Feb; one ♀ with one foetus was recorded in Apr, and an immature ♂ was recorded in May. These data suggest that litter-size is one and that the reproductive chronology is polyoestry, but this needs confirmation.

Conservation IUCN Category: Least Concern.

Bergmans (1999) indicated that this listing would be appropriate because of the wide distribution of this species in the Rainforest BZ in central Africa and its apparent abundance in one of the better-searched localities (Irangi). Major threat: deforestation.

Measurements

GENUS *Eidolon*

Straw-coloured Fruit Bats

Eidolon Rafinesque, 1815. Analyse de la Nature, p. 54. Type species: *Vespertilio vampirus helvus* Kerr, 1792.

Eidolon is a polytypic genus with two species: *E. helvum* on mainland Africa, *E. dupreanum* on Madagascar. Diagnostic characters: no white markings on head; no white basal ear-patches; adult ♂♂ without epaulettes; FA: 105–135 mm; no red or yellow mantle contrasting with blackish-brown dorsal pelage, no ruff of stiff hairs around the neck; five upper and six lower cheekteeth (Table 11, p. 228). The palatal ridges and craniodental characters of *Eidolon helvum* are illustrated in Figure 38.

The genus was revised by Bergmans (1990). *Eidolon* was placed in the *Rousettus* section of Andersen (1912a), and in the subfamily Rousettinae (tribe Rousettini) by Bergmans (1997). Juste *et al.*

(1999) indicate that *Eidolon* is not phylogenetically related to any other African fruit bat. Giannini & Simmons (2005) recovered *Eidolon* as sister to a pteropodine clade (including *Acerodon*, *Pteralopex* and *Pteropus*) in some but not all analyses, suggesting that more data are needed to corroborate this hypothesis and its interesting biogeographic implications. Based on this and other recent studies, the position of *Eidolon* is considered uncertain by Simmons (2005).

The African species is *Eidolon helvum*.

Meredith Happold

Figure 38. African *Eidolon*. Palatal ridges of *E. helvum*. Skull of *E. helvum* (BMNH 98.10.24.2, adult ♂).

Eidolon helvum AFRICAN STRAW-COLOURED FRUIT BAT

Fr. Rousette des palmiers africaine; Ger. Afrikanischer Palmflughund

Eidolon helvum (Kerr, 1792). In: Linnaeus, Anim. Kingdom 1 (1): xvii, 91. Senegal.

Taxonomy Originally *Vespertilio vampyrus helvus*. Synonyms: *annobonensis*, *buettikoferi*, *leucomelas*, *mollipilosus*, *paleaceus*, *palmarum*, *sabaeum*, *stramineus*. Hayman & Hill (1971) also included *dupreanum* from Madagascar, but Bergmans (1990) regards *E. dupreanum* as a distinct species. Subspecies: two, but only the nominate in Africa. Chromosome number: $2n = 34$ (Matthey 1962); aFN not known.

Description Large, yellowish fruit bat with no basal ear-patches; no white markings on head; no red or yellow mantle contrasting with dorsal pelage; no ruff of stiff hairs (although longer, pale yellowish-brown to bright orange hairs on throat); FA: 105–135 mm. Little sexual dimorphism. Hairs 6–8 mm mid-dorsally, longer ventrally; dorsal pelage extending to half-way along forearm (but not on to wing-membranes) and narrowing on mid-back (between wing-membranes); sparse on head. Dorsal pelage variable between individuals and between different regions of body; can be dull yellow, brownish-yellow, pale yellowish-grey to dark sepia-grey, or dull brown; head darker than shoulders, interscapular region and rump often darker and less yellow than mid-dorsal region and adjacent to wing-membranes; hairs pale yellowish, mostly tipped with brown or greyish-brown. Ventral pelage (except on throat) grading from pale yellow (buff) on flanks to pale brown mid-ventrally. Throat with ruff of longer (but not stiff) hairs, ranging from pale yellowish-brown to bright orange; breeding ♂ brighter than ♀. Males without epaulettes. Head

without markings; muzzle long, narrow, almost naked; cheeks only moderately extensible; lips fine and smooth. Ears rounded, naked, dark brown. Eyes large, orange-brown. Palate with four undivided thick ridges followed by four divided, serrated, thin ridges (Figure 38). Wing-membranes dark brown (in marked contrast to dorsal pelage), inserting unusually high on back (for an African fruit bat) and attaching to first toe. Thumb very long with a powerful, sickle-shaped, hook-like claw. Legs strikingly long. Interfemoral membrane narrow (especially near tail). Tail relatively long for a fruit bat.

Skull (Figure 38), on average, medium-long for an African fruit bat. Braincase domed, rostrum of medium relative length for this family; premaxillae not fused anteriorly. Basicranial axis considerably deflected; upper alveolar line straight. Tympanic bulla protruding to form a short tube around the auditory meatus. M_1 comparatively long (length = combined length of M_2 and M_3) (cf. *Rousettus* and *Lissonycteris*). Dental formula $2^{132}/_{2133} = 34$.

Geographic Variation Two subspecies are recognized by Bergmans (1990): *E. h. helvum* in Africa and *E. h. sabaeum* in SW Arabia. Geographic variation in size in Africa is not apparent, but detailed investigations have not yet been undertaken. Four specimens (♂♂) from Bioko I. (Eisentraut 1964) have comparatively large skulls (GLS: 55.8–58.7 mm). Unconfirmed records from Somalia possibly represent *E. h. sabaeum* (Bergmans 1990).

Similar Species Two other large African fruit bats have no basal ear-patches and no white markings on head; FA: >108 mm:

Pteropus voeltzkowi. Dorsal pelage blackish-brown with bright rusty-red or rusty-orange mantle. Larger (FA: 145–163 mm). Pemba I. only.

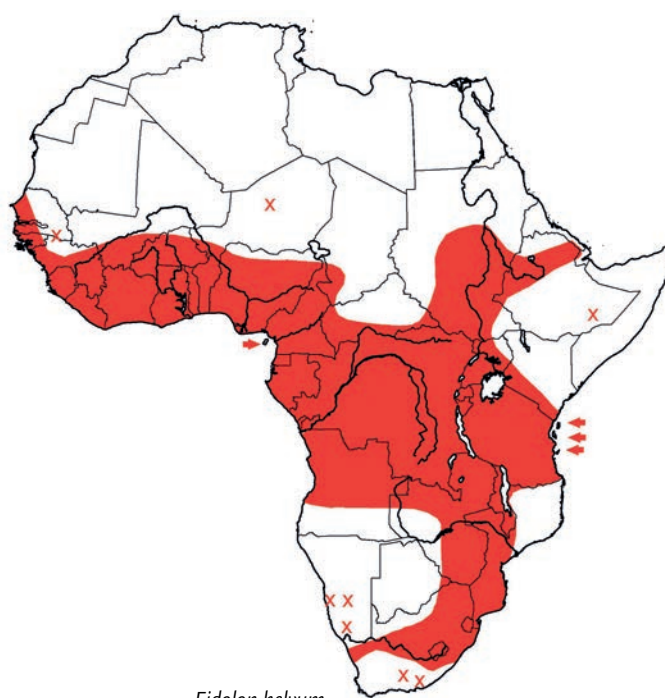

P. seychellensis comorensis. Dorsal pelage blackish-brown with golden or rusty-yellow mantle. Larger (FA: 147–158 mm). Mafia I.

Distribution In Africa, this migratory species has been recorded from all countries and all biotic zones and mosaics south of the Sahara (except the South-West Cape BZ), but there are no records in most parts of the Sahel Savanna, Somalia–Masai Bushland and South-West Arid BZs and also in some large parts of the Sudan Savanna, Guinea Savanna and Zambezian Woodland BZs. Some authors (e.g. Kingdon 1974, DeFrees & Wilson 1988) suggest that the Rainforest BZ, and the Rainforest–Savanna Mosaics and the Coastal Forest Mosaic BZ, from West Africa to East Africa (including Zanzibar, Mafia and Pemba Is.) comprise ‘prime habitat’ from which colonies migrate seasonally into the dry forest, woodland savanna and Sahel zones, and only reach the northern and southern limits seasonally and/or irregularly. Although Bergmans (1990) maintains that this is an overgeneralization that ignores the absence of records from very large parts of the area involved, this view is not held here. Extraliminally: SW Arabian Peninsula.

Habitat Probably inhabits all forest and woodland savanna habitats when and where trees are producing succulent fruits.

Abundance Extremely abundant locally, with largest colonies in forest regions possibly exceeding 1 million, and with one colony in savanna at Kasanka N. P., Zambia reaching 5–10 million (see below). Huge colonies are often associated with tall trees in city parks, making this fruit bat the most observable bat in Africa. Seasonally abundant to irregular at northern and southern limits due to fragmentation of colonies during seasonal migrations (Thomas 1983, Cosson *et al.* 1996). Comparatively rare in mist-netting samples taken at ground level because these fruit bats usually fly fairly high.

Adaptations Aspect ratio medium-low; wing-loading exceptionally high; wing-tip slightly pointed (Norberg & Rayner 1987). Flight straight and comparatively non-agile; slow, regular wing-beats often interrupted by short glides; mean speed (tested indoors) 4.5 m/sec (Rosevear 1965, Kulzer 1968 in Norberg 1987), but wing morphology and personal observations suggest that flight speeds are considerably higher in the field. Must dive 1–2 m to gain sufficient speed for flight, which might explain preference for canopy foraging. Makes long-range migrations: ♂♂ tracked by satellite telemetry are known to migrate at least 2000 km in three months, from Kasanka N. P., Zambia (where the bats presumably aggregate to exploit an exceptional rich seasonal peak in food) to N DR Congo (Richter & Cumming 2008); no data for ♀♀. Has been recorded at sea 240 km from land (Rosevear 1965). Remarkably long thumbs and legs facilitate agile climbing. By day, usually roosts colonially in tall trees exposed to full sunlight, but one small colony roosted on rock face of escarpment in C Mali (Thomas 1983). Heart very large, with massive anterior vena cava, allowing great flight endurance.

Eidolon helvum

Anastomoses permit regulation of blood flow into wing-membranes, probably to allow off-loading of heat during long-distance flight and mid-day roosting. Shows well-developed wing-licking and wing-fanning when roosting in full sun. Exhibits a strong homeothermic response down to 10°C, but rapidly becomes hypothermic below 10°C. Tongue has long backward-directed papillae, probably to facilitate rapid collecting of nectar. Skin of the neck contains a large sebaceous gland complex, better developed in ♂♂ than in ♀♀, suggesting that the throat ruff provides olfactory cues (Mainoya & Howell 1979).

Foraging and Food At dusk, colonies become active; groups fly up to 100–200 m above ground and non-migrating individuals forage as far as 59 km from the roost in one night (Richter & Cumming 2008). Commonly feeds in noisy groups. Diet includes great diversity of flowers (10 genera, 6 families), fruits (33 genera, 23 families) and leaves (4 genera, 3 families) (Marshall 1985). Unusual in specializing on small figs and small fruits (5–15 mm diameter), including *Ficus vogellii* and berries *Bridelia ferruginea*. Good climbing agility may make the harvesting of small fruits economical.

Social and Reproductive Behaviour Roosts in groups (colonies) varying in size from tens to hundreds of thousands, sometimes ca. 1 million and, in Kasanka N. P., Zambia, colonies of 5–10 million assemble each year in Nov–Dec (Richter & Cumming 2008). Cycles in colony occupation and size are intimately associated with migrations and reproductive chronology. North of Equator, colonies in rainforest habitats reach peak size at onset of dry season in northern savannas (Sep–Oct at Kampala, Uganda; Oct–Nov at Abidjan, Côte d'Ivoire). Colonies include juveniles and yearlings until Nov–Dec (Kampala), when these age-groups may disperse elsewhere (Kingdon 1974). Pregnant ♀♀ and adult ♂♂ remain until births (Jan–Feb at Abidjan; Feb–Mar at Kampala) and mating (probably Feb at Abidjan; Apr–Jun at Kampala). North of Equator,

colonies in forest habitats disperse with northward progression of rains into the savanna (Feb–Mar at Abidjan; May–Jun at Kampala). Migration into the savanna occurs in groups that fragment, creating progressively smaller colonies as they move northwards to at least 13° N (Thomas 1983). During the pregnancy and parturition period, multi-female groups associate with one or few ♂♂, suggesting polygyny and harem-formation, but the associations appear labile. There are no detailed studies of social structure in colonies.

Reproduction and Population Structure Litter-size: normally one ($n = \text{ca. } 200$); twins reported once. In Uganda, Nigeria and Côte d'Ivoire, the reproductive chronology is restricted seasonal monoestry with delayed implantation – a chronology not known in any other African fruit bat. At 00° 20' N (Kampala, Uganda), copulation and fertilization occur in Apr–Jun followed by development to blastocyst stage and then delayed implantation for ca. three months (during migration); implantation and onset of developmental gestation in Oct; births ca. four months later (Feb–Mar); lactation for ca. one month (Mutere 1965, 1967). Males gain mass prior to the mating season, suggesting increase in body condition. At Kampala, rain falls throughout the year but there are peaks in Oct–Nov and Apr–May, and the reproductive chronology is such that both spermatogenesis and lactation coincide with periods of high rainfall, and births during the relatively dry periods are avoided. At 07° 30' N (Ife, Nigeria), copulation and fertilization occur in May–Jul; implantation in Nov after a delay of ca. five months; births in Mar–Apr (Fayenuwo & Halstead 1974, Funmilayo 1979 in Bernard & Cumming 1997). At Ife, there is a long wet season (Mar–Jun), a short wet season (Sep–Oct) and a hot dry season (Nov–Feb). Here, both spermatogenesis and lactation occur during the long wet season, and the longer period of delayed implantation ensures that births do not occur until the long wet season is well established. At Ife, implantation coincides exactly with the start of the hot dry season, which suggests that the sudden change in weather or body condition might provide the stimulus for implantation (Fayenuwo & Halstead 1974). In contrast, at Kampala, implantation does not appear to coincide with any marked climatic factor. Reproduction south of the Equator has not been documented; an austral cycle is predicted but needs confirmation.

Predators, Parasites and Diseases Snakes, carnivorous birds (African Eagle-owl *Bubo africanus* and Kite *Milvus migrans*) and

mammals (Palm Civet *Nandinia binotata*, genets *Genetta* spp., even Potto *Perodicticus potto*) are probable predators, but few observations of non-human predation exist. Hunters with shotguns, and boys with sling-shots, kill large numbers (hundreds) for personal consumption or sale in markets. Ectoparasites include: a bed-bug *Afrocmex constrictus* (Hemiptera: Cimicidae); three species of fleas (Siphonaptera: Ischnopsyllidae); six species of bat-flies (Diptera: Nycteribiidae); pentastomids *Armillifer* sp. (Pentastomida: Porocephalidae), *Linguatula* sp. (Pentastomida: Linguatulidae); two species of ticks (Acari: Argasidae, Ixodidae); and 12 species of mites (Acari: Spinturnicidae, Macronyssidae, Myobiidae, Ereynetidae, Chirodiscidae, Sarcoptidae, Gastronyssidae, Teinocoptidae) (Anciaux de Faveaux 1984). Can harbour the following viruses: Bunyamwera, Entebbe bat, Lagos bat, West Nile, Yellow Fever, Zika and others (Anciaux de Faveaux 1984).

Conservation IUCN Category: Near Threatened.

Often seen in large numbers but the population of this species is declining because of over-harvesting for food and medicine.

GENUS *Epomophorus*

Epauletted Fruit Bats

Epomophorus Bennett, 1836. Proc. Zool. Soc. Lond. 1835: 149 [publ. 1836]. Type species: *Pteropus gambianus* Ogilby, 1835.

Epomophorus is a polytypic genus, endemic to Africa (with the exception that *E. labiatus* also occurs in SW Saudi Arabia). Diagnostic characters: white basal ear-patches but no other white markings on the head; epaulettes on shoulders of adult ♂♂; FA: 54–100 mm; muzzle simple; interfemoral membrane well developed and with calcars; six thick palatal ridges; usually three upper and five lower cheekteeth (very occasionally four upper cheekteeth) (Table 11, p. 228). Palatal ridges of six species are illustrated in Figure 39. The skull of a representative of the genus is illustrated in Figure 40,

but there are inter-specific variations, especially in size and relative dimensions (see below). *Epomophorus* has eight species, more than any other genus of fruit bat endemic to Africa. Seven of the species occur mainly in savanna woodland habitats, one species occurs in both forest and savanna habitats.

Epomophorus was placed in the *Epomophorus* section of Andersen (1912a), and in the subfamily Epomophorinae (tribe Epomophorini) of Bergmans (1997) together with *Epomops*, *Hypsiphatius* and *Micropteropus*, which seem closely related morphologically and

Figure 39. Palatal ridges of six species of *Epomophorus*. (a) *Epomophorus angolensis*, (b) *E. crypturus*, (c) *E. gambianus*, (d) *E. grandis* (based on Bergmans 1988 with permission of the author), (e) *E. labiatus* and (f) *E. wahlbergi*.

karyotypically (Haiduk *et al.* 1980). *Nanonycteris*, which was not studied by Haiduk *et al.* (1980), was also placed in this tribe by Bergmans (1997). However, more recently, the monophyly of the Epomophorinae (*sensu* Bergmans 1997) has been questioned (up to now, only by Springer *et al.* 1995 and Romagnoli & Springer 2000) and, pending a thorough revision of the Pteropodidae, Simmons (2005) does not recognize any of these subfamilial or tribal groups.

Andersen (1912a) recognized eight species: *E. gambianus*, *E. wahlbergi*, *E. labiatus*, *E. crypturus*, *E. angolensis*, *E. anurus*, *E. minor* and *E. pousarguesi*. Subsequently, *E. reii*, *E. grandis* (previously *Micropteropus grandis*) and *E. anelli* were added to this list. *Epomophorus wahlbergi*, *E. angolensis* and *E. grandis* have been regarded consistently as well-defined species, but the systematics of the other species has been controversial. These fall into two groups, one containing the larger species *E. gambianus*, *E. crypturus*, *E. pousarguesi* and *E. reii*, and the second containing the smaller species *E. anurus*, *E. labiatus*, *E. minor* and *E. anelli*.

Epomophorus labiatus. ♂ during courtship.

On the basis of standard measurements and qualitative characters, Bergmans (1988) concluded that *crypturus* was a synonym of *E. gambianus*, that *reii* was a synonym of *E. g. gambianus*, and that *pousarguesi* was a subspecies of *E. gambianus*. Subsequently, on the basis of zoogeography and the univariate and multivariate analyses of skull characters, Claessen & DeVree (1990a) concluded that both *E. crypturus* and *E. gambianus* were well-defined species and that *reii* and *pousarguesi* are synonyms of *E. gambianus*. There

Figure 40. Skull of *Epomophorus wahlbergi* (BMNH 64.1.9.5, adult ♂).

are only four ‘*pousarguesi*’ specimens. They come from a different habitat and possibly belong to an isolated population, but their dimensions overlap with those of the largest specimens of *E. gambianus* and therefore Claessen & De Vree (1990a) concluded that it is premature to give these specimens subspecific rank. The specific status of *E. crypturus* is not widely accepted (e.g. Koopman 1993, Bergmans 1997), but this form is presented here as a distinct species partly because this is the most convenient option pending resolution of its true status. Simmons (2005), who also presents *E. crypturus* as a distinct species, points out that genetic studies, and more collecting in the wide gap between the distributions of *crypturus* and *gambianus*, may be necessary to resolve the relationship between these taxa.

Bergmans (1988) tentatively recognized both *E. labiatus* and *E. minor* but he discussed the status relationships of these species and regarded his arrangement as temporary. Bergmans (1988) also considered that *anurus* was a synonym of *E. labiatus*. Subsequently, on the basis of multivariate and discriminant analyses, Claessen & De Vree (1990b) concluded that *E. anurus*, *E. labiatus* and *E. minor* separated into two groups: a first group with an obvious clinal variation in size, consisting of specimens formerly identified as *E. anurus*, *E. labiatus* and partly as *E. minor*, and a second group with no geographic variation in size, consisting of specimens formerly identified as *E. minor*. They identified the first group as representatives of *E. labiatus*, and placed the second

group into a new species *E. minimus*. Bergmans (1997) accepted *E. minimus*, but indicated that there are several problems associated with *E. labiatus* as defined by Claessen & De Vree (1990b) (see species profile *E. labiatus*). Finally, in 2004, Bergmans & Van Strien described, as a new species named *E. anelli*, two specimens from Malawi, which are intermediate in size between specimens of *E. crypturus* and Malawian specimens of *E. labiatus*.

For convenience, we tentatively recognize eight species but acknowledge that the status of *E. crypturus* is uncertain, and that the content of *E. labiatus* is controversial. Most of these species can be distinguished by the characteristics and information given in Table 12. Differences in skull shape are derived from the relative dimensions listed in Table 13. *Epomophorus labiatus* and *E. minimus* can usually be distinguished by the length of their skulls: GLS: >36.5 mm (♀ ♀) or GLS: >40.0 mm (♂ ♂) indicates *E. labiatus*. In N Tanzania, however, these species are not easily distinguished. Claessen & De Vree (1990b) published a discriminant function for this purpose but, according to N. P. Giannini & N. B. Simmons (pers. comm.), it is flawed and not reliable.

The species are placed in three species-groups following Simmons (2005), but presented in alphabetical order irrespective of their species-groups.

Meredith Happold

Table 12. Key to the species in the genus *Epomophorus*. For an explanation of the diagnostic characteristics of the palatal ridges, see Family Pteropodidae. Size categories are based on the ranges of mean forearm lengths and mean GLS exemplified by the genus *Epomophorus*. Ranges are as currently known, but data for some species are derived from very small samples: *E. angolensis* (for FA, n = 9, for GLS, n = 6), *E. anelli* (n = 3 including one not fully adult ♀) and *E. grandis* (n = 3).

| Number of thick postdental palatal ridges | Palatal ridges 2, 3 & 4 | Size FA (mm) | Size GLS (mm) | Miscellaneous | Species |
|---|-------------------------|--|--|---|----------------------|
| 1 | Not divided | Large
♂ ♂ 81.9 (72–95)
♀ ♀ 78.1 (67–88) | Medium
♂ ♂ 50.5 (44.4–57.3)
♀ ♀ 44.8 (41.0–49.3) | | <i>E. wahlbergi</i> |
| 1 | Divided | Small
♂ ♂ 62, 63
♀ ♀ 66 | Small
♂ ♂ 35.4, 36.7
♀ ♀ 36.4 | | <i>E. grandis</i> |
| 2 in ♂
1 plus 1 partly postdental in ♀ ♀ | Not divided | Medium
♂ ♂ 77
♀ ♀ 68 >74 | Medium
♂ ♂ 47.1
♀ ♀ 38.7, > 41.2 | As yet known only from Malawi and SW Tanzania. In these localities, probably distinguished from <i>E. labiatus</i> by size | <i>E. anelli</i> |
| 2 | Not divided | Large
♂ ♂ 88.2 (85–94)
♀ ♀ 83.3 (81–86) | Large
♂ ♂ 56.4, 60.0
♀ ♀ 50.1 (49.4–50.6) | 4th palatal ridge nearer 3rd than 5th
Angola, Namibia; west of 18° E | <i>E. angolensis</i> |
| 2 | Not divided | Large
♂ ♂ 88.5 (80–100)
♀ ♀ 83.3 (75–95) | Large
♂ ♂ 58.7 (51.8–63.6)
♀ ♀ 50.8 (44.0–56.8) | 4th palatal ridge mid-way between 3rd and 5th
Distributed north of 4° N | <i>E. gambianus</i> |
| 2 | Not divided | Large
♂ ♂ 84.5 (80–88)
♀ ♀ 79.0 (75–83) | Large
♂ ♂ 53.6 (51.8–55.7)
♀ ♀ 46.1 (44.0–48.8) | 4th palatal ridge mid-way between 3rd and 5th
Distributed south of 8° S and east of 18° E | <i>E. crypturus</i> |
| 2 | Not divided | Medium
♂ ♂ 69.4 (60–80)
♀ ♀ 68.3 (58–76) | Small–Medium
♂ ♂ 42.7 (35.4–48.6)
♀ ♀ 39.3 (33.5–46.0) | In N Tanzania, not easily distinguished from <i>E. minimus</i> . Elsewhere GLS > 36.5 mm (♀ ♀), >40.0 mm (♂ ♂). In Malawi (and probably SW Tanzania), distinguished from <i>E. anelli</i> by size (see Similar Species) | <i>E. labiatus</i> |
| 2 | Not divided | Small
♂ ♂ 61.6 (54–67)
♀ ♀ 60.4 (57–66) | Small
♂ ♂ 35.7 (32.9–39.0)
♀ ♀ 33.3 (31.2–36.4) | In N Tanzania, not easily distinguished from <i>E. labiatus</i> . Elsewhere GLS < 36.5 mm (♀ ♀), < 40.0 mm (♂ ♂) | <i>E. minimus</i> |

Table 13. Relative dimensions of the skull in species of *Epomophorus* (based on Bergmans 1988). ZW = zygomatic width, GLS = greatest length of skull, RL = rostrum length, Pal = palatal length and C–C = width across upper canines (see Bergmans 1988 for definitions of these parameters). Sample size given in brackets.

| Species | <i>E. angolensis</i> | <i>E. anselli</i> | <i>E. crypturus</i> | <i>E. gambianus</i> | <i>E. grandis</i> | <i>E. labiatus</i> | <i>E. minimus</i> | <i>E. wahlbergi</i> |

Epomophorus angolensis ANGOLAN EPAULETTED FRUIT BAT

Fr. Épomophore d'Angola; Ger. Angola-Epaulettenflughund

Epomophorus angolensis Gray, 1870. Cat. Monkeys, Lemurs, Fruit-eating Bats Brit. Mus., p. 125. Benguela, Angola.

Taxonomy Species-group: *gambianus*. Synonyms: none. Chromosome number: not known.

Description Small to medium-sized, dorsally pale to medium brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂ ♂; six palatal ridges of which two are postdental and fourth is closer to third than to fifth. Sexes with some differences in colour; ♂ ♂ mostly larger than ♀ ♀. Pelage soft, slightly fluffy; extending (dorsally and ventrally) ca. half-way along forearm; mid-dorsal hairs ca. 10 mm. Dorsal pelage pale brown to medium reddish-brown, sometimes paler on shoulders; hairs darker reddish-brown at base. Ventral pelage paler except, in adult ♂ ♂, chin, throat and chest are darker reddish-brown and this colour extends dorsally to form a ring around each epaulette. Adult ♂ ♂ with a white epaulette on each shoulder (retracted into pouch except when displayed). Head dog-like with anterior and posterior whitish basal ear-patches. Muzzle relatively long and narrow for an *Epomophorus*; lips and cheeks fleshy and expansible (especially in ♂ ♂). Ears short, rounded, dark brown. Eyes large. Palate with four thick interdental and two thick postdental ridges, the fourth closer to the third than the fifth (Figure 39a) (cf. *E. crypturus*); ridges 2, 3 and 4 not divided (cf. *E. grandis*). Wing-membranes brown; attaching to second toe. Tail absent or very short.

Skull on average medium-sized for an African fruit bat; large for an *Epomophorus*. Zygomatic width relatively narrow; rostrum relatively long and narrow, and palate of medium relative length for an *Epomophorus* (Table 13, p. 237). Postdental palate markedly concave (cf. *Epomops*). Dental formula $^{2121}/_{2132} = 28$.

Geographic Variation Based on its relatively restricted and continuous distribution, geographic variation is unlikely (Bergmans 1988).

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂ ♂ with epaulettes; three upper and five lower cheekteeth; only nine occur south of the Equator:

Epomophorus angolensis

Epomophorus crypturus. Fourth palatal ridge mid-way between third and fifth ridges. East of 18° E.

E. anselli and *E. labiatus*. Smaller (Table 12, p. 236).

E. wahlbergi. Only one thick postdental palatal ridge.

E. grandis. Much smaller (Table 12).

E. minimus. Much smaller (Table 12).

Epomops dobsonii. Three thick interdental palatal ridges.

Micropteropus (2 spp.). Much smaller (FA: 46–64 mm).

Distribution Endemic to Africa. Zambezi Woodland BZ and marginally in the north of the South-West Arid BZ, in W and SW Angola and Ovamboland in N Namibia (Bergmans 1988). An outlying record from 'Swakopmund', Namibia (not mapped) was queried by Shortridge (1934) and Bergmans (1988).

Habitat Known from drier regions than other species of *Epomophorus*, although probably found mainly in riverine habitats within these regions, e.g. reported roosting in exposed situations in *Acacia* trees along the Cunene R. by Shortridge (1934). The holotype was collected from Bushy Karoo–Namib scrubland at Benguela, Angola. Other records are from wetter miombo woodland, undifferentiated woodland, mopane woodland and the transition from mopane woodland to Bushy Karoo–Namib scrubland (Bergmans 1988; terminology from White 1983).

Abundance Uncertain; considered ‘Rare’ by Mickleburgh *et al.* (1992).

Remarks Individuals were observed hanging from the bare branches of large *Acacia* trees near the Cunene R. in Namibia; they were exposed to direct sunlight (Shortridge 1934). Five of six adult ♀♀ taken in Sep or Oct at Cunene R. (ca. 17° 20' S) had swollen nipples and appeared to be lactating, and of these, two had single neonates clinging to them (Shortridge 1934 and evidence from his specimens in BMNH).

Conservation IUCN Category: Near Threatened.

Provisionally listed as such because its population may be declining significantly and because of the loss of riverine roosting and fruit trees.

Measurements

Epomophorus angolensis

FA (♂♂): 88.2 (85–94) mm, n = 4

FA (♀♀): 83.3 (81–86) mm, n = 5

WS (d): 670 mm, n = 1

HB (♂): 158 mm, n = 1

HB (♀♀): 146 (130–155) mm, n = 12

T: (♂): 5 mm, n = 1

T: (♀♀): 3.3 (3–5) mm, n = 6

E (♂): 28 mm, n = 1

E (♀♀): 24 (23–26) mm, n = 12

Tib (♂♂): 36.8 (36–39) mm, n = 4

Tib (♀♀): 37.6 (32–39) mm, n = 7

HF: n. d.

WT: n. d.

GLS (♂♂): 56.4, 60.0 mm, n = 2*

GLS (♀♀): 50.1 (49.4–50.6) mm, n = 4*

GWS (♂): 27.4 mm, n = 1*

GWS (♀): 25.1 mm, n = 1*

C–M¹ (♂♂): 19.5 (17.0–21.6) mm, n = 4*

C–M¹ (♀♀): 17.4 (17.1–17.9) mm, n = 5*

Angola and Namibia (BMNH, Shortridge 1934, Hill & Carter 1941, *Bergmans 1988)

Two of the four ♀♀ skulls have fractures, which might have affected their GLS

Epomophorus anelli ANSELL'S EPAULETTED FRUIT BAT

Fr. Épomophore d'Ansell; Ger. Ansell's Epaulettenflughund

Epomophorus anelli Bergmans and Van Strien, 2004. Acta Chiropterologica 6: 258. Lisanthu (13° 00' S, 33° 10' E), 1000 m, Kasungu N. P., Malawi.

Taxonomy Species-group: *gambianus*. Described from two specimens from Kasungu N. P., Malawi. A further two specimens (from Karonga, Malawi) almost certainly represent *E. anelli*, and three other specimens from Karonga are possibly referable, or partly referable, to this species (Bergmans & Van Strien 2004). Recognized as a valid species, although its describers considered the possibility that the specimens of *E. anelli* may be hybrids of *E. crypturus* and *E. labiatus*. These two species are found sympatrically at both localities in Malawi from which the form *anelli* has been recorded, and *anelli* is intermediate in size (Bergmans & Van Strien 2004). However, at one of these localities (Karonza), five *E. labiatus*, possibly 4–5 *E. anelli* (but identity not certain) and two *E. crypturus* were obtained, side by side, during two days of collecting and, in this collection, the proportion of specimens probably representing *E. anelli* appears too high for it to be a hybrid unless an extraordinary and highly unlikely amount of interbreeding had occurred. Synonyms: none. The holotype has been referred to as *Epomophorus anurus* by Bergmans & Jachmann (1983), *E. crypturus* by Happold *et al.* (1987) and *E. labiatus* by Bergmans (1988) and Claessen & De Vree (1990b). Subsequently, a further specimen was found, this time from SW Tanzania (NMW B5112; W. Bergmans unpubl.). This specimen was first identified as *E. minor*, then as *E. wahlbergi*, then published as *E. labiatus* (Bergmans 1988). Chromosome number: not known.

Description Small, medium brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; six palatal ridges of which, in ♂, two are postdental and in ♀ the fifth is partly interdental and the sixth postdental. A poorly known species with only one adult ♂, one nearly adult ♀ and one adult ♀ known; identity of some more specimens awaits confirmation. Males apparently larger than ♀♀ and with dark band on the chest. Pelage soft; mid-dorsal hairs 12–15 mm; extending dorsally and ventrally along each upper arm and up to a third of each forearm. Dorsal pelage medium brown (fawn); hairs very slightly darker brown at base. Ventral pelage very pale brown mid-ventrally, becoming slightly darker on flanks; no whitish mid-ventral patch; adult ♂ with dark brown band high on the chest, running transversely between the epaulettes. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed). Ears relatively short (26–28% of FA, n = 2), rounded, naked, brown with dark brown rim. Anterior and posterior white basal ear-patches present. Muzzle moderately long and broad. Lips and cheeks fleshy and very expansible, especially in ♂♂. Palate in ♂ with four thick, undivided interdental ridges and two thick divided postdental ridges, the fourth mid-way between third and fifth (cf. *E. angolensis*); in both ♀♀, the fifth ridge is only partly postdental. Wing-membranes brown; attaching to second toe. Tail very short.

Skull medium-sized for an African fruit bat; medium-sized in ♂ but short in ♀♀ for an *Epomophorus*. Zygomatic width medium for this genus; rostrum of medium relative length and breadth in one ♂, but relatively short and broad in one ♀; palate relatively short (Table 13, p. 237). Postdental palate markedly concave (cf. *Epomops*). Dental formula $^{2121}/_{2132} = 28$.

Geographic Variation Not known.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Epomophorus grandis. Six thick palatal ridges of which 2–6 are divided.

Apparently smaller, but data are limited (Table 12, p. 236).

E. angolensis. Larger (Table 12).

E. crypturus. Apparently slightly larger (Table 12).

E. labiatus. In Malawi (and probably SW Tanzania), smaller (FA ♂♂: 60–67 mm, n = 19, FA ♀♀: 58–65 mm, n = 15; GLS ♂♂: 35.4–40.3 mm, n = 16, GLS ♀♀: 33.2–37.7 mm, n = 15).

E. wahlbergi. Fifth palatal ridge interdental. On average larger (Table 12).

E. gambianus. Apparently slightly larger (Table 12). North of Equator.

E. minimus. Smaller (Table 12). Nearest record N Tanzania.

Epomops (3 spp.). Three or five thick palatal ridges.

Micropteropus (2 spp.). Smaller (FA: 46–64 mm).

Nanonycteris veldkampii. Much smaller (FA: 46–54 mm). North of Equator.

Distribution Endemic to Africa. Known with certainty only from Lisanthu (13°00'S, 33°10'E) in Kasungu N. P., Malawi (the type locality), from Lifupa Camp (13°05'S, 33°08'E) in Kasungu N. P., Malawi, and from Ugano (10°56'S, 35°00'E) in SW Tanzania (Bergmans & Van Strien 2004, Bergmans unpubl.). The Tanzanian locality became known too late to be mapped. Almost certainly, it has also been recorded from Karonga (09°56'S, 33°56'E), Malawi (Bergmans & Van Strien 2004). All of these localities are in the Zambezian Woodland BZ but the Tanzanian locality is on the edge of the Afromontane–Afroalpine BZ.

Habitat The holotype was captured at 1000 m, over a stream between two Water Berry trees *Syzygium cordatum*, which were bearing fruit. Both Lisanthu and Lifupa Camp are located at 1000–1100 m, in wetter Zambezian miombo woodland dominated by *Brachystegia* and *Julbernardia* (Bergmans & Jachmann 1983; terminology: White 1983). Details of habitat at Karonga are not known. The Tanzanian locality, at 1560 m, lies on the boundary between wetter Zambezian miombo woodland and undifferentiated afromontane vegetation (terminology: White 1983).

Abundance Not known. Only two specimens (the holotype and paratype from Kasungu N. P.) are known with certainty from Malawi. Two others from Malawi (from Karonga) almost certainly represent this species, and there are three other specimens from Karonga, some or all of which might represent this species (details in Bergmans & Van Strien 2004). The Tanzanian specimen appears to be the only one known from that country.

Epomophorus anelli

Remarks Within Kasungu N. P., *E. anelli* has been collected at the same locality as *Epomophorus labiatus*, *Epomops dobsonii* and *Eidolon helvum*, while *Epomophorus crypturus* (as *E. gambianus crypturus*) was collected less than 2 km away in similar vegetation (Bergmans & Van Strien 2004). At Karonga, *Epomophorus anelli* has been collected at the same time as *E. crypturus*, *E. labiatus* and *E. wahlbergi* (MMB). The diet possibly includes fruits of *Syzygium cordatum*, but this needs confirmation. The ♂ holotype, collected on 19 Mar, had scrotal testes of 8.2 mm in length (measured through the skin). The nearly adult ♀ paratype was collected on 19 May, and the adult ♀ from Tanzania, collected in Jun, had large nipples, suggesting lactation at time of capture.

Conservation IUCN Category: Data Deficient.

Although very few specimens are known, and although they come from only three areas within a small rectangle between 09°56'S and 13°05'S, and 33°08'E and 35°00'E, there is no reason to believe that this species is in any danger. Furthermore, the available data are few and based on specimens collected between 1961 and 1988.

Malawi and Tanzania (measurements of holotype [adult ♂, ZMA

21.693b], paratype [nearly adult ♀, ZMA 26.105] and Tanzanian specimen [adult ♀, NMW B5112], respectively)

The Tanzanian specimen is prepared as skull and skin, and the forearm bones and skull are damaged and incomplete – hence the approximate FA and GLS measurements and lack of other measurements

Epomophorus crypturus PETERS'S EPAULETTED FRUIT BAT

Fr. Épomophore de Peters; Ger. Peters' Epaulettenflughund

Epomophorus crypturus Peters, 1852. Naturwissenschaftliche Reise nach Mossambique. Zoologie I. Säugetiere.
Georg Reimer, Berlin. Tete, Mozambique.

Taxonomy Species-group: *gambianus*. Synonyms: *parvus*. Subspecies: none. On the basis of standard measurements and qualitative characters, *crypturus* is considered a subspecies of *E. gambianus* by Bergmans (1988). However, on the basis of univariate and multivariate analyses and geographical distribution, *E. crypturus* is considered to be a well-defined species by Claessen & De Vree (1990a). Bergmans (1997) gives reasons for rejecting the arguments of Claessen & De Vree (1990a). Simmons (2005) suggests that genetic studies and further collecting between the geographic ranges of the two taxa may be necessary to resolve their relationship. Here, the status of *crypturus* is considered uncertain, but it is tentatively treated as a distinct species because it is easier to combine data from two species, if they are later shown to be conspecific, than vice-versa. Chromosome number (Zimbabwe): $2n = 35$ (♂♂), 36 (♀♀); aFN = 68 (Peterson & Nagorsen 1975).

Description Small to medium-sized, pale brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; six palatal ridges of which two are postdental; fourth ridge mid-way between third and fifth ridges. Males on average larger and with darker throat than ♀♀. Pelage soft, slightly fluffy; extending dorsally and ventrally along each upper arm and some distance along each forearm; mid-dorsal hairs 10–11 mm. Dorsal pelage usually pale brown (fawn), paler on shoulders and often suffused with yellow on head, neck and rump; hairs dark brown at base. Some individuals (usually ♂♂) are darker (almost sepia brown) and some much paler (as though bleached). Ventral pelage slightly to considerably paler than dorsal pelage; throat sometimes rusty-brown, especially in adult ♂♂. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed). Head dog-like with anterior and posterior white basal ear-patches. Muzzle relatively very long and broad, especially in ♂♂. Lips and cheeks fleshy and very expansible, especially in ♂♂. Ears relatively short (26–36% of FA, $n = 8$), rounded, naked, brown with dark brown rim. Eyes large, brown. Palate with four thick interdental and two thick postdental ridges, the fourth mid-way between third and fifth (Figure 39b) (cf. *E. angolensis*); ridges 2, 3 and 4 not divided (cf. *E. grandis*). Wing-membranes brown; attaching to second toe. Tail absent or very short.

Skull medium-sized for an African fruit bat; long and robust for an *Epomophorus*. Zygomatic width relatively narrow for this genus; rostrum relatively long and broad (♂♂) or of medium breadth (♀♀); palate relatively long (Table 13, p. 237). Postdental palate markedly concave (cf. *Epomops*). Dental formula $^{2121}/_{2132} = 28$.

Key Reference Bergmans & Van Strien 2004.

Wim Bergmans

Geographic Variation None recorded.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

- Epomophorus angolensis*. Fourth palatal ridge nearer to third ridge than fifth. Angola, Namibia, west of 18° E.
- E. anelli*. Apparently slightly smaller (Table 12, p. 236) but data very limited.
- E. labiatus*. Almost always smaller (Table 12).
- E. wahlbergi*. Only one postdental palatal ridge (but *E. anelli* ♀♀ also have only one).
- E. grandis*. Smaller (Table 12).
- E. minimus*. Smaller (Table 12).
- E. gambianus*. North of Equator.
- Epomops* (3 spp.). Three or five thick palatal ridges.
- Micropteropus* (2 spp.). Much smaller (FA: 46–64 mm).
- Nanonycteris*. Much smaller (FA: 46–54 mm). North of Equator.

Distribution Endemic to Africa. Zambezan Woodland BZ and Coastal Forest Mosaic BZ. Recorded from E Angola to coast of Mozambique and from S Tanzania to E South Africa (Bergmans 1988 as *E. gambianus crypturus*). Indentations in the distribution might reflect insufficient sampling in those areas or, especially in Zambia and S Mozambique, the prevalence of less favourable drier habitats.

Habitat Apparently restricted to tropical and sub-tropical woodland savannas (including undifferentiated woodland and wooded grassland, and miombo), and the coastal forest mosaics of East Africa. Often found where evergreen trees are present, and sometimes follows riverine forests into drier regions. Not usually found in drier associations of *Colophospermum mopane*, *Acacia* spp. or *Terminalia* (Smithers 1983), although recorded from mopane woodland in Zimbabwe (Volpers & Kumirai 1995).

Abundance Common to very common, but local numbers are determined by the seasonal availability of fruits.

Adaptations Aspect ratio low; wing-loading very high (M. Happold unpubl.). Flight fast and direct in the open, slow and highly manoeuvrable through dense foliage. Can hover briefly and take off from the ground. Locomotion over flat surfaces is extremely awkward, and clambering around branches has not been reported. By day, hangs

Epomophorus crypturus

from small branches and twigs, shaded by foliage, usually in the canopies of evergreen trees. In Zimbabwe, commonly roosts in wild fig-trees *Ficus* spp. and sausage-trees *Kigelia africana*. At one locality, two radio-tracked individuals roosted in different trees on five of six consecutive days (Thomas & Fenton 1978). The wings, especially the thumbs and wrists, are used for holding and manipulating food. The tongue, which is used for lapping nectar from flowers and juice from fruits, is long with rasp-like backward-pointing papillae near the tip. The kidney has a thin medulla and no protruding papilla (as in *E. wahlbergi*, Figure 29a), enabling production of dilute urine.

Foraging and Food Feeds on soft fruits and/or nectar of trees. When visiting flowers, individuals hang on with their feet, and often support themselves by flapping their wings while lapping nectar with their long tongues. Sometimes roosts within half a kilometre of food, and movements (followed by radio-tracking) were confined to the vicinity of these resources over a period of six days (Thomas & Fenton 1978). During this study, *E. crypturus* began foraging almost two hours earlier than cave-dwelling *Rousettus aegyptiacus*, which had to commute from much further away, but subsequently both species fed together. Sometimes also feeds with *Epomophorus labiatus*, *E. wahlbergi* and/or *Epomops dobsonii*. At some localities *E. crypturus* seems to come and go, suggesting nomadic movements in response to seasonal changes in abundance of food (Pienaar *et al.* 1980, Smithers 1983). Apparently feeds opportunistically on the soft fruits and/or nectar of at least 20 species of trees (listed by Mickleburgh *et al.* 1992). Accumulations of skins, seeds and chewed pulp under some fruiting trees where this species feeds indicate that only the juices of the fruits are swallowed. Fruits eaten include orchard and garden soft-fruits such as guavas, apricots, peaches, loquats and papayas, but not hard-fruits such as apples and pears. This avoidance of hard-fruits implies that soft-fruits are only eaten when they are fully ripe and therefore over-ripe for commercial harvesting. If this is correct, *E. crypturus* probably helps to control fungal diseases and fruit-flies (see Tuttle 1986). In Zimbabwe

during the dry season, apparently specializes on only a few fruit-bearing trees (e.g. *Parinari curatellifolia*) (Volpers & Kumirai 1995).

Social and Reproductive Behaviour Roosts singly or in groups, which may be small to very large (several hundreds). Individuals space themselves at least 0.3 m apart and contact is negligible (except between mothers and young). When these bats fly into a roost at dawn, there is much bickering and the clawed thumbs on the wings are used to slash out at other bats that attempt to hang too close (Smithers 1983). Mating-system not known. Males make a moderately loud bell-like 'pink' repeated frequently (Volpers & Kumirai 1995). They are known to call at their roosts soon after dusk, but there appears to be no published observations of any associated displays, or mating, at the roosts or elsewhere.

Reproduction and Population Structure Litter-size: one, perhaps twins very rarely. Reproductive chronology not known. Lactation recorded in summer (Nov–Jan) in the former Transvaal (Pienaar *et al.* 1980) and in the wet season (Nov, Mar and Apr) in Malawi and E Zambia (Happold & Happold 1990a) but no conclusive data for other months. In Zimbabwe, pregnancies were recorded Jul–Mar with a particularly high proportion (73%) in Aug, and no pregnancies were recorded in Apr–Jun: this suggested a Sep peak in births (Smithers & Wilson 1979, Smithers 1983), but embryo size and lactation were not recorded and therefore year-round timing of births cannot be determined from this information. It has been suggested (e.g. Mickleburgh *et al.* 1992) that ♀♀ have one litter/year, but this cannot be confirmed from the above data. Young are born with eyes closed, sparse dorsal pelage, no ventral pelage, weight ca. 11 g. Each neonate attaches itself to one of its mother's two pectoral nipples, and clings with well-developed hindfeet and thumbs to its mother's pelage. For some time, juveniles are carried while their mothers forage. When too big to carry conveniently, they are left at a roost while the mothers forage.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Epomophorus gambianus GAMBIAN EPAULETTED FRUIT BAT

Fr. Épomophore de Gambie; Ger. Gambia-Epaulettenflughund

Epomophorus gambianus (Ogilby, 1835). Proc. Zool. Soc. Lond. 1835: 100. Gambia.

Taxonomy Originally *Pteropus gambianus*. Species-group: *gambianus*. Synonyms: *epomophorus*, *guineensis*, *macrocephalus*, *megacephalus*, *pousarguesi*, *reii*, *whitei*, *zechi*. Subspecies: two recognized here; Bergmans (1988) also recognized *crypturus* as a subspecies, but this taxon is treated here as a distinct species. Chromosome number: not known.

Description Small to medium-sized, pale brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; six palatal ridges of which two are postdental. Males larger, on average, than ♀♀ and often with dark brown necks and chests. Pelage soft, slightly fluffy; extending dorsally and ventrally along each upper arm and some distance along each forearm; mid-dorsal hairs ca. 10 mm. Dorsal pelage usually pale brown (fawn), paler on shoulders and often suffused with yellow on head, neck and/or rump; hairs dark brown at base. Some individuals (especially ♂♂) are darker (almost sepia brown) and some much paler (as though bleached). Ventral pelage slightly to considerably paler than dorsal pelage: ♂♂ sometimes with a pale or white ventral patch. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed). Head dog-like with anterior and posterior white basal ear-patches. Muzzle relatively long (especially in ♂♂), and narrow. Lips and cheeks fleshy and very expansible, especially in ♂♂. Ears relatively short (22–32% of FA, n = 41), rounded, naked, brown with dark brown rim. Eyes large, brown. Palate with four thick interdental and two thick postdental ridges, the fourth mid-way between third and fifth; ridges 2, 3 and 4 not divided (cf. *E. grandis*) (Figure 39c). Wing-membranes brown; attaching to second toe. Tail absent or very short.

Skull long and robust for an *Epomophorus*. Zygomatic width relatively narrow (♂♂) or of medium relative width (♀♀); rostrum relatively long and narrow in both sexes, and palate relatively long for this genus (Table 13, p. 237). Postdental palate extremely concave (cf. *Epomops*). Dental formula $^{2121}_{2132} = 28$.

Geographic Variation Two of the three subspecies recognized by Bergmans (1988) are listed below. Possibly, *crypturus* is also a subspecies of *E. gambianus* but, here, this form is tentatively treated as a distinct species (see profile).

Epomophorus g. gambianus: Senegal to Ethiopia, excluding part of Central African Republic. Smaller (FA ♂♂: 81–95 mm, FA ♀♀: 76–90 mm; GLS ♂♂: 53.3–62.5 mm, GLS ♀♀: 46.1–55.4 mm).

E. g. pousarguesi: Four specimens, collected in Central African Republic at ca. 4°N and 18–19°E in Guinea-Congo lowland rainforest/secondary grassland mosaic, are considered to represent a distinct subspecies by Bergmans (1988), but Claessen & De Vree (1990a)

consider *pousarguesi* to be a synonym of *E. gambianus*. Larger (FA ♂: 100 mm, FA [n = 3 ♀♀]: 91–95 mm; GLS ♂: 63.6 mm, GLS [n = 3 ♀♀]: 54.4–56.8 mm).

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Epomophorus crypturus. South of Equator.

E. angolensis. Fourth palatal ridge closer to third ridge than fifth. South of Equator.

E. wahlbergi. Only one postdental palatal ridge.

E. anelli. Apparently slightly smaller (Table 12, p. 236) but data are limited.

E. grandis. Smaller (Table 12). One postdental palatal ridge; ridges 2, 3 and 4 divided. South of Equator.

E. minimus. Much smaller (Table 12).

E. labiatus. Almost always smaller (Table 12).

Epomops (3 spp.). Three or five thick palatal ridges.

Micropteropus (2 spp.). Much smaller (FA: 46–64 mm).

Nanonycteris veldkampii. Much smaller (FA: 46–54 mm).

Distribution Endemic to Africa. Mainly Sudan and Guinea Savanna BZs and the Northern Rainforest–Savanna Mosaic from Senegal to Central African Republic, and the Afromontane–Afroalpine BZ of Ethiopia. The gap between 23–35°E probably reflects insufficient sampling in that area. The outlying locality marked with a cross in CAR is that of *E. g. pousarguesi*. Map based on Bergmans (1988).

Habitat A woodland savanna species rarely found syntopically with forest fruit bats even though it also colonizes forest–savanna mosaics and derived savanna habitats in the Rainforest BZ, and sometimes also exploits fringes of rainforest habitats (Bergmans 1988). In West Africa, mainly found in *Isobrerlinia* woodland and undifferentiated woodland, and in forest–grassland mosaics bordering the rainforest. There are some records from drier types of lowland rainforest and mangrove forest, but probably in areas cleared for farming. Localities along the West African coast are in forest–grassland mosaics. In Sudan and Ethiopia, found in woodland and transitions to deciduous bushland and wooded grasslands, and also in afromontane vegetation, evergreen and semi-evergreen bushland and thicket (Bergmans 1988; terminology from White 1983).

Abundance Well represented in collections; probably common throughout most of geographic range when and where fruiting and/or flowering trees are present.

Epomophorus gambianus

Adaptations Aspect ratio very low; wing-loading high. Flight fast and direct in the open, slow and manoeuvrable through dense foliage. Can hover briefly. By day, hangs from small branches and twigs, shaded by foliage, usually high in the canopy of the tallest savanna trees. Several species of trees are used, including *Khaya senegalensis*, *Kigelia africana*, *Azadirachta indica*, *Mangifera* sp., *Cola* sp. and *Ficus* spp. (Boulay & Robbins 1989). The wings, especially the thumbs and wrists, are used for holding and manipulating food. The long tongue is used for lapping nectar from flowers and juice from fruits. This species has been seen skimming over rivers, close enough to drink water directly or by wetting the pelage and then licking it, but there is no certainty that this behaviour serves to obtain water for drinking (Bergmans 1978).

Foraging and Food Feeds on soft fruits and nectar. Usually forages earlier in the evening than some of the species (e.g. *Nanonycteris veldkampii*) with which it competes (Baker & Harris 1957, 1959). At other times, it arrives and feeds with *N. veldkampii* and *Micropteropus pusillus*. Foraging occurs throughout the night. At some localities, *E. gambianus* is nomadic in response to seasonal changes in the abundance of food (Happold & Happold 1978). Individuals visiting flowers hang on with their feet, and often support themselves by flapping the wings, while the nectar is lapped with the long tongue. Feeds opportunistically on soft fruits of endemic and cultivated trees and on the nectar (but apparently not the pollen or flowers) of several trees, including some whose flowers are adapted for pollination by fruit bats. In West Africa, obtains food from at least 18 species (listed in Mickleburgh *et al.* 1992). More species are utilized during the wet season, when resources are abundant, than in the dry season (Thomas & Marshall 1984). *Epomophorus gambianus* plays an important role in the dispersal of tree seeds and the regeneration of abandoned farmlands: the seeds of eight species were found in the faeces of individuals from Wango Fitini, Côte d'Ivoire (Thomas & Marshall 1984). Laps nectar from

the flowers of *Ceiba pentandra* and *Parkia clappertoniana* (Baker & Harris 1957, 1959), *Adansonia digitata*, *Kigelia africana* and mango trees. Like other nectar-lapping fruit bats, it collects pollen on its pelage and may transfer it to other flowers. Probably pollinates *Parkia*, but its importance (compared with that of other fruit bats) as a pollinator of other species of trees is not known.

Social and Reproductive Behaviour Roosts singly or in groups of two to more than 100 (Marshall & McWilliam 1982). Individuals space themselves at least 0.3 m apart and contact is negligible (except between a mother and her young). Some 'traditional' roosts are used year after year although individuals may change roosts every few days and nomadic movements sometimes result in these roosts being periodically deserted. These bats return to their roosts at first light; from sunrise to sunset there is silence and little movement except for occasional grooming. At sunset, they start flying about the roost and 'quarrelsome' calls are uttered if individuals come too close together. Adult ♂♂ may hang from perches and perform a calling-display during which they utter a moderately loud bell-like 'ping' at intervals of 1–3 seconds, display their epaulettes, and beat their wings in the interval between each call. Calling-displays at the roost may last up to 35 minutes. Individuals leave the roost singly or in groups, and may forage singly or in groups (including mixed-species groups). During the night, adult ♂♂ perform more calling-displays of up to three hours' duration, at sites remote from the roost. The calling-displays of this species probably attract ♀♀ and culminate in mating (as in *Hypsignathus*) but this needs confirmation and, even so, the mating system will not necessarily be lekking (see *Hypsignathus monstrosus*). The calling-displays and concomitant mating behaviour attributed to *E. gambianus* by Tuttle (1986) must be that of another species of *Epomophorus* (presumably *E. wahlbergi*) because *E. gambianus* does not occur in Kenya where his observations were made.

Reproduction and Population Structure Litter-size: normally one. At 09° 50' N (Wango Fitini, Comoé N. P., Côte d'Ivoire), the reproductive chronology of *E. g. gambianus* is continuous bimodal polyoestry with postpartum oestrus. Each ♀ has two litters/year. Gestation 5–6 months. Females are in reproductive synchrony; young are born during two seasons of parturition – at the beginning of the single wet season (Apr) and at the end of the wet season (Oct). Consequently both lactations occur when 3–6 species of fruit are available, cf. 2–3 in dry season (Thomas & Marshall 1984). At ca. 10° N (Mole N. P., Ghana), births occur at beginning of wet season (no data for other months) (Marshall & McWilliam 1982). Other published records from West Africa are inconclusive.

Predators, Parasites and Diseases While raising their young, Pied Crows *Corvus albus* sometimes prey on roosting *E. gambianus*. Ectoparasites include bat-flies *Cyclopodia greeffi*, *Eucampsipoda africana* (Diptera: Nycteribiidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Epomophorus grandis SANBORN'S EPAULETTED FRUIT BAT

Fr. Épomophore de Sanborn; Ger. Sanborns Epaulettenflughund

Epomophorus grandis (Sanborn, 1950). Publções Companhia de Diamantes de Angola 10: 55. Dundo, Lunda, Angola.

Taxonomy Originally *Micropteropus grandis*. Species-group: *grandis*. Synonyms: none. Transferred from *Micropteropus* to *Epomophorus* by Bergmans (1988). Chromosome number: not known.

Description Small, pale brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; six palatal ridges of which numbers 2–6 are divided and only one is postdental. A poorly known species – only three adults and one juvenile known. Sexual dimorphism: no conclusive data. Pelage dense dorsally, sparser ventrally. Dorsal pelage pale reddish-brown; hairs slightly darker at base (W. Bergmans pers. comm.). Ventral pelage very pale brown to whitish-brown. Throat nearly naked. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed). Head pale brown without markings except for anterior and posterior white basal ear-patches. Muzzle longish, although relatively short and broad for an *Epomophorus*. Lips and cheeks of ♂♂ fleshy and expansible (no data for ♀♀). Ears relatively short, slightly pointed, naked with brown pigmentation. Eyes large. Palate with six thick ridges of which 2–6 are divided by medial gap, 5 is level with last molars and 6 is postdental (Figure 39d). In juveniles, palatal ridges 2–4 are not divided. Wing-membranes light brown; attaching to second toe. Tail absent or very short.

Skull short for an African fruit bat and for an *Epomophorus*. Zygomatic width relatively large, rostrum relatively short and broad, and palate relatively short for this genus (Table 13, p. 237); rostrum of medium relative length for an African fruit bat. Postdental palate weakly concave (N. P. Giannini pers. comm.). Dental formula $2^{121}/_{2132} = 28$.

Geographic Variation None recorded.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Epomophorus anselli. Six thick palatal ridges of which only 5 and 6 are divided. Apparently larger, but data are limited (Table 12, p. 236).

E. crypturus. Larger (FA: >70 mm; GLS: >40 mm).

E. angolensis. Much larger (Table 12).

E. wahlbergi. Larger (Table 12). Only one thick postdental palatal ridge.

E. minimus. Two thick postdental palatal ridges; ridges 2, 3 and 4 not divided. East Africa, Ethiopia, Somalia.

E. gambianus. Larger (Table 12). Two postdental palatal ridges; ridges 2, 3 and 4 not divided. North of Equator.

E. labiatus. Two thick postdental palatal ridges; ridges 2, 3 and 4 not divided.

Epomops (3 species). Three or five thick palatal ridges.

Micropteropus intermedius. Smaller in most skull and tooth dimensions including, in particular, rostrum length (11.2–11.6 mm), palatal length (17.3–18.5 mm) and C–M¹ (10.2–10.6 mm). Of the six palatal ridges, only 5 and 6 are divided.

M. pusillus. Smaller (FA: 46–55 mm; GLS: <32 mm).

Nanonycteris veldkampii. Smaller (FA: 46–54 mm).

Distribution Endemic to Africa. Known only from two localities in the Southern Rainforest–Savanna Mosaic: Dundo near northern border of Angola, and Pointe Noire on coast of Congo.

Habitat The above localities lie just south of the Rainforest BZ, where long fingers of rainforest project along the river valleys into secondary grasslands and woodland savannas (Hayman 1963, Bergmans 1988). Not recorded from the rainforest itself. The specimen from Pointe Noire was mist-netted in a stand of *Borassus* palms and lower shrubs behind the beach (Bergmans 1979). Bergmans (1988) predicts that *E. grandis* is a woodland species that might also be found in woodland savanna habitats E and S of the two known localities.

Abundance Only three adults and one juvenile have been collected, but this species perhaps occurs in some parts of the Zambezian Woodland BZ where few collections have been made.

Remarks The holotype, collected in Sep, was carrying a juvenile with milk teeth and FA: 46 mm (Sanborn 1950), suggesting this birth occurred shortly before the wet season.

Epomophorus grandis

Conservation IUCN Category: Data Deficient.

No evidence of rarity in the field; habitat preferences, distributional limits and population dynamics not known (Bergmans 1999). The area where it occurs has been inaccessible for years.

Meredith Happold

Epomophorus labiatus LITTLE EPAULETTED FRUIT BAT

Fr. Épomophore de Temminck; Ger. Temmincks Epaulettenflughund

Epomophorus labiatus (Temminck, 1837). Monogr. Mamm., 2: 83. Given as 'Abyssinia', but probably Sennar, Blue Nile Province, Sudan (see Bergmans 1988, p. 105).

Taxonomy Originally *Pteropus labiatus*. Species-group: *gambianus*. Claessen & De Vree (1990b) conducted principal component analyses of skull measurements of specimens previously identified as *E. anurus*, *E. labiatus* and *E. minor*, and concluded that only two groups were represented by the material examined. The first group (a cluster of larger specimens with geographic variation in size) consisted of specimens formerly identified as *E. anurus*, *E. labiatus* and partly as *E. minor*, and these were considered to represent *E. labiatus*. The second group (a cluster of small specimens with no geographic variation in size) consisted of specimens formerly identified as *E. minor*, and these were described as a new species, *E. minimus*. While tentatively accepting the validity of *E. minimus*, Bergmans (1997) points out that there are many unresolved problems with *E. labiatus* as defined by Claessen & De Vree (1990b). Bergmans (1997) raised the possibility that *E. labiatus* (*sensu* Claessen & De Vree 1990b) contained more than one species and subsequently described *E. anelli*, the holotype of which was considered to represent *E. labiatus* by Claessen & De Vree (1990b). It is possible that *E. labiatus sensu* (Claessen & De Vree 1990b) contains still more species but, until the taxonomy of the small *Epomophorus* is fully resolved, information for all of the forms (excluding *E. minimus* and *E. anelli*) is given in the following profile. Synonyms:

anurus, *doriae*, *minor*, *schoensis*, *schovanus*. Subspecies: none. For a specimen formerly referred to as *E. anurus*, chromosome number (W Uganda): $2n = 36$ (♀) (Dulić & Mutere 1973a).

Description Small, pale brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; six palatal ridges. Not easily identified by its size and palatal ridges (see Similar Species). Males often darker and, on average, slightly larger than ♀♀. Pelage soft, fluffy; extending dorsally and ventrally along each upper arm and for some distance along each forearm; mid-dorsal hairs ca. 10 mm. Dorsal pelage (♂♂) pale brown; hairs pale brown with dark brown at base. Ventral pelage (♂♂) pale brown merging into pure white on abdomen; some ♂♂ with dark brown shoulders and throat. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed). Dorsal pelage (♀♀) pale brown (fawn); hairs beige with pale brown at tip. Ventral pelage (♀♀) pale fawn on chest becoming darker on abdomen. Head dog-like with anterior and posterior white basal ear-patches. Muzzle longish, although relatively medium-short and broad for an *Epomophorus*. Lips and cheeks fleshy and very expansible, especially in ♂♂. Ears relatively short, rounded, naked, brown with dark

brown rim. Eyes large, brown. Palate with six thick ridges, the fourth mid-way between third and fifth, the fifth partly or fully postdental and the sixth postdental; ridges 2, 3 and 4 not divided (cf. *E. grandis*) (Figure 39e). Wing-membranes brown; attaching to second toe. Tail very short or absent.

Skull medium (♂♂) or short (♀♀) for an African fruit bat and for an *Epomophorus*, and of medium relative breadth for this genus (Table 13, p. 237). Rostrum relatively short and broad (♀♀), also broad but possibly a little longer in ♂♂ (based on data for both *E. labiatus sensu* Bergmans and *E. minor* in Bergmans 1988). Postdental palate moderately concave. Dental formula $\frac{2121}{2132} = 28$.

Geographic Variation Clinal geographic variation in skull length is characteristic of this species as defined by Claessen & De Vree (1990b). However, some data were ignored when it was concluded that the variation was clinal, and the variation may also reflect the existence of more than one species in *E. labiatus* (Bergmans 1997).

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Epomophorus anelli. In Malawi (and probably SW Tanzania), larger (FA ♂♂: 77 mm, FA ♀♀: 68, >74 mm; GLS ♂♂: 47.1 mm, GLS ♀♀: 38.7, >41.2 mm).

E. crypturus. Almost always larger (Table 12, p. 236).

E. angolensis. Larger (Table 12).

E. wahlbergi. Only one thick postdental palatal ridge.

E. grandis. Only one thick postdental palatal ridge; ridges 2, 3 and 4 divided.

E. minimus: Skull usually shorter (GLS ♂♂: almost always <40 mm, GLS ♀♀: almost always <36.5 mm). In NTanzania, differences are minimal and the discriminate function of Claessen & DeVree (1990b) is flawed (see Genus *Epomophorus* and see also Bergmans 1997).

E. gambianus. Almost always larger (Table 12).

Epomops (3 spp.). Three or five thick palatal ridges.

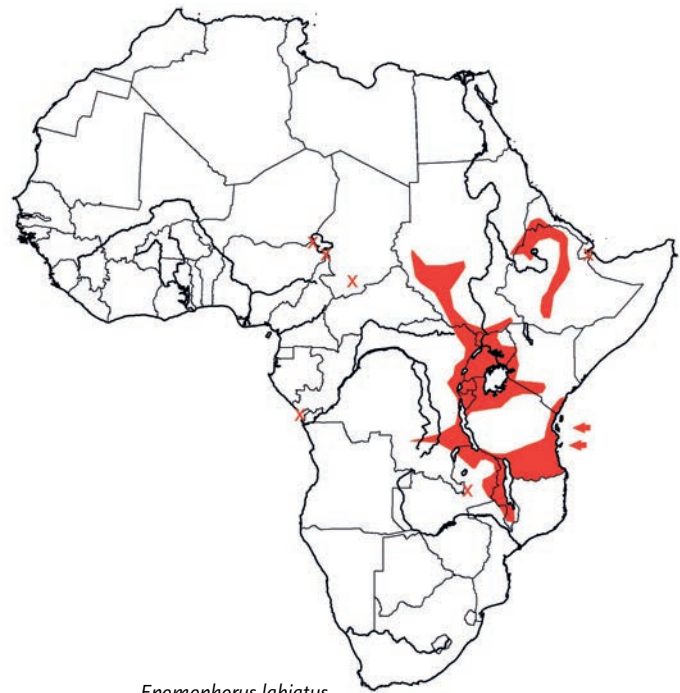

Micropteropus intermedius. Palatal ridges 2–4 divided by medial gap.

M. pusillus. Smaller (FA: 46–56 mm).

Nanonycteris veldkampii. Smaller (FA: 46–54 mm).

Distribution Mainly found in the Sudan and Guinea Savanna BZs, all Rainforest–Savanna Mosaics and the Coastal Forest Mosaic BZ, the Zambesian Woodland BZ and (in Ethiopia) the Afromontane–Afroalpine BZ, but apparently not widespread in any zone except the Eastern Rainforest–Savanna Mosaic. Recorded from NE Nigeria and S Congo eastwards to Djibouti, Eritrea and the Tanzanian coast (including Mafia I.; Kock & Stanley 2009), and southwards to Malawi. Extraliminally: SW Saudi Arabia (Gaucher 1992). Map adapted from Claessen & de Vree (1990b) with additional records from Bergmans (1988): this map should be regarded as tentative pending resolution of taxonomic problems.

Habitat Found in a wide variety of savannas including undifferentiated woodland, wetter miombo woodland, evergreen and semi-evergreen bushlands, *Acacia–Commiphora* deciduous bushland and thicket and *Acacia* wooded grassland (Bergmans 1988; terminology from White 1983). Also found in a variety of mosaics,

Epomophorus labiatus

(including rainforest–savanna, coastal forest–savanna, and evergreen bushland–grassland) and afromontane vegetation (Bergmans 1988). In Saudi Arabia, found in juniper forest at 2200 m from May to Sep but presumably moves to lower altitudes during the colder months (Gaucher 1992).

Abundance Well represented in collections. Probably common throughout most of its range but local abundance may depend on seasonal availability of fruit and flowers.

Adaptations Aspect ratio very low; wing-loading medium. Flight fast and direct when commuting, or slow with considerable manoeuvrability when foraging through the canopies of trees. Can hover briefly and take off from the ground. Locomotion over ground is extremely awkward – the wings flap in synchrony and the hindfeet are not used. Can clamber along thin branches and can climb head-first up or down rough surfaces: in both cases, the bat holds on with the thumbs and hindfeet and moves the wings and hindfeet in alternation (M. Happold pers. obs.). By day, hangs freely from branches of trees and shrubs (usually but not always under dense foliage), under banana leaves, and from roots exposed by the erosion of river-banks (Verschuren 1957). The thumbs and second fingers are opposable and are used with great dexterity during feeding (see below). The thumbs are also used to hold onto a perch while the bat hangs, with legs dangling, to defecate or urinate. Defaecation and urination also occur during flight. The tongue is long with small, rasp-like, backward-pointing papillae near the tip. During grooming, it is protruded from the front or sides of the mouth and used to lick the face, genital region and both surfaces of the wings. The claws of the hindfeet are used to comb the dorsal and ventral pelage, and individuals also shake themselves during grooming. Captive individuals did not drink.

Foraging and Food Primarily frugivorous. In Malawi, *E. labiatus* feeds on wild figs, and sometimes visits trees at the same

time as *E. crypturus* and *E. wahlbergi* (M. Happold unpubl.). Lands on clusters of figs and uses the thumbs and second fingers in conjunction to pull food towards the mouth and, subsequently, to hold and manipulate it while it is chewed. Food is initially packed into the expansible cheeks, carried to a perch and then chewed slowly, small amounts at a time. If a bat is hanging while feeding, one hindfoot is sometimes used to manipulate food in the mouth. Captive bats land to eat fruit on the ground suggesting that fallen fruits might be collected in the wild. Captive bats feed at intervals throughout the night. Feeds on soft fruits of endemic and cultivated trees including *Ficus*, *Terminalia*, *Mangifera*, *Irvingia* and *Salvadoria* (Verschuren 1957, 1965a, Okia 1974a, Mickleburgh *et al.* 1992). Visits the flowers of *Parkia* and *Kigelia*, but it is not known what components are eaten.

Social and Reproductive Behaviour Often roosts singly. Also observed roosting in groups of up to 40, but the individuals were 'hanging singly or scattered amid the branches of a grove of trees' (Lang & Chapin 1917b as *E. anurus*). Adult ♂♂ probably perform calling-displays as do other epauletted fruit bats, but the larynx is not very large and the calls can be heard only a short distance. A captive ♀ called intermittently throughout each night of her week in captivity (M. Happold unpubl.). The call was a soft bell-like 'ping' uttered at intervals of 1–7 seconds. A similar 'ping' made by an electronic watch elicited 'pinging' by the bat.

Reproduction and Population Structure Litter-size: one. At 00° 05'N (Entebbe) and 01° 30'N (Sebei, Uganda), the reproductive chronology is continuous bimodal polyoestry with postpartum oestrus (Okia 1974a). Gestation 5–6 months. Females are in reproductive synchrony. Parturition and postpartum mating occur in late Mar to early Apr, and late Sep to early Oct. Uganda has two wet seasons (Mar–May and Oct–Dec), so lactation and early pregnancy occur during each wet season. The relationship between reproductive chronology and availability of food is not known. Birth-weight ca. 11 g. At ca. 8–15°S in Malawi and Zambia, where there is one wet season (Nov to early Apr), ♀♀ are not in reproductive synchrony. Births have been recorded from Oct–Feb (no data for other months) (Happold & Happold 1990a as *E. minor*). Pregnant ♀♀ (n = 2), which appeared to have been lactating recently, were recorded in Oct and late-Jan, suggesting polyoestry, but this needs confirmation. In the Shire Highlands (Malawi), although young were mist-netted in Mar–May, no adults were mist-netted from Mar–Jun, or in Sep (no data for Jul–Aug), suggesting these bats are sometimes nomadic. If bimodal polyoestry occurs in this population, the first and second litters are presumably born at different localities.

Predators, Parasites and Diseases Predators include Silvery-cheeked Hornbill *Bycanistes brevis* (Kingdon 1973). Ectoparasites include a bat-fly *Basilia blainvillii* (Diptera: Nycteribiidae) and 11 species of mites (Acari: Spinturnicidae, Myobiidae, Trombiculidae, Ereynetidae, Chirodiscidae, Sarcoptidae, Gastronyssidae, Teinocoptidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Epomophorus labiatus.

Epomophorus minimus LEAST EPAULETTED FRUIT BAT

Fr. Épomophore nain; Ger. Winziger Epaulettenflughund

Epomophorus minimus Claessen and De Vree, 1991. Senckenberg. Biol. 71: 209–238. Bahadu, Shewa, Ethiopia.

Taxonomy Species-group: *gambianus*. Synonyms: none. Included in *E. minor* by Bergmans (1988), but considered to be a distinct species by Claessen & De Vree (1990b); for details, see *E. labiatus*. Chromosome number: not known.

Description Small, fawn fruit bat with anterior and posterior white basal ear-patches and epaulettes on adult ♂♂, which very closely resembles *E. labiatus* (see profile). There are six thick palatal ridges; both fifth and sixth are fully postdental; ridges 2, 3 and 4 are not divided (cf. *E. grandis*). The skull is short for an *Epomophorus* and, in both sexes, the zygomatic width is relatively large (Table 13, p. 237). Postdental palate almost flat. Dental formula $^{2121}_{2132} = 28$.

Geographic Variation None recorded. No geographic variation in skull length (cf. *E. labiatus*).

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Epomophorus angolensis and *E. gambianus*. Much larger (Table 12, p. 236).

E. crypturus. Larger (FA: >70 mm; GLS >40 mm).

E. anelli. Larger (Table 12). Nearest record Malawi.

E. wahlbergi. Only one postdental palatal ridge. Larger (FA: almost always >67 mm; GLS: >40 mm).

E. grandis. Only one postdental palatal ridge; ridges 2, 3 and 4 divided. Congo, Angola.

E. labiatus. Skull usually longer (GLS ♂♂: almost always >40 mm, GLS ♀♀: almost always >36.5 mm). In N Tanzania, differences are minimal and the discriminate function of Claessen & De Vree (1990b) is flawed (see Genus *Epomophorus* and also Bergmans 1997).

Epomops (3 spp.). Three or five thick palatal ridges.

Micropteropus (2 spp.). Palatal ridges 2–4 divided by median gap.

Nanonycteris veldkampii. Smaller (FA ♂♂: 46–52 mm, FA ♀♀: 47–54 mm). Nine thick or partly thick palatal ridges.

Distribution Endemic to Africa. Known from ca. 40 localities, mostly in the Sudan Savanna and Afromontane–Afroalpine BZs, in C Ethiopia, C, N and E Kenya, and Somalia (Claessen & De Vree 1990b). Also recently recorded from the northern and western floral regions of W Uganda (Kityo & Kerbis 1996). Discontinuities in the distribution probably reflect insufficient sampling.

Habitat Poorly known. Most localities appear to be in deciduous bushland and thicket dominated by *Acacia* and *Commiphora* (usually near rivers and/or highlands), or in afromontane vegetation on the slopes of the Ethiopian and Kenyan Highlands. Also penetrates marginally into semi-desert grasslands and shrublands, but probably stays near rivers. In W Uganda, *E. minimus* is common in mosaics

*Epomophorus minimus*

of savanna and riverine forest in the northern floral region and less common in blocks of lowland rainforest in the western floral region (Kityo & Kerbis 1996).

Abundance Kityo & Kerbis (1996) reported *E. minimus* to be the second most abundant bat (after *Micropteropus pusillus*) in the northern floral region of Uganda. No information from elsewhere.

Remarks *Epomophorus minimus* is a newly described species that cannot be distinguished easily from *Epomophorus labiatus* with which it is sympatric in some areas. There appear to be no recent, detailed studies of its biology. Because species in the *E. anurus–labiatus–minor* complex were confused prior to the work of Claessen & De Vree (1990b), and because the taxonomy of species in this complex (which now includes *E. anelli*) is not yet fully resolved, observations in areas where these species occur sympatrically *Epomophorus* must be treated with caution.

Conservation IUCN Category: Least Concern.

***Epomophorus wahlbergi* WAHLBERG'S EPAULETTED FRUIT BAT**

Fr. Épomophore de Wahlberg; Ger. Wahlbergs Epaulettenflughund

Epomophorus wahlbergi (Sundevall, 1846). Ofv. Kongl. Svenska Vet.-Akad. Forhandl. Stockholm 3: 118.
 Near Durban, KwaZulu–Natal, South Africa.

Taxonomy Originally *Pteropus wahlbergi*. Species-group: *wahlbergi*. Synonyms: *haldemani*, *neumanni*, *stuhlmanni*, *unicolor*, *zenkeri*. Subspecies: two of dubious validity. Chromosome number (Kenya, Zimbabwe): 2n = 36; aFN = 68 (Dulić & Mutere 1973a, Peterson & Nagorsen 1975).

Description Small to medium-sized, fawn fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂ ♂; six thick palatal ridges of which only one is postdental. Males on average larger than ♀ ♀, sometimes darker, sometimes with band of brown pelage around epaulettes and across throat and around testes (when sexually active). Pelage soft, slightly fluffy; extending dorsally and ventrally along each upper arm and for some distance along each forearm; mid-dorsal hairs ca. 10 mm. Dorsal pelage fawn, paler on shoulders, sometimes suffused with yellow on hindlimbs and around tail (especially in ♀ ♀); hairs (on back) fawn with dark brown at base. Ventral pelage slightly to considerably paler, sometimes suffused with grey. Adult ♂ ♂ with white epaulette on each shoulder (retracted into pouch except when displayed). Head dog-like with anterior and posterior white basal ear-patches. Muzzle long (although relatively short and broad for an *Epomophorus*). Lips and cheeks fleshy and very expansible, especially in ♂ ♂; ♂ ♂ can be distinguished at a distance by their expansible cheeks, which appear to form a pad under each eye. Ears relatively short, rounded, naked, brown with dark rim. Eyes large, brown. Palate with five thick interdental ridges and one thick postdental ridge; ridges 2, 3 and 4 not divided (cf. *E. grandis*) (Figure 39f): in exceptional cases, the fifth ridge is partly postdental. Wing-membranes brown; attaching to second toe. Tail absent or very short.

Skull (Figure 40) medium-sized for an African fruit bat but long and robust for an *Epomophorus*. Zygomatic width relatively large, rostrum relatively short and broad, and palate relatively short for this genus (Table 13, p. 237). Postdental palate markedly concave. Dental formula $^{2121}/_{2132} = 28$.

Geographic Variation Two subspecies, *E. w. wahlbergi* and *E. w. haldemani* have been described, but their ranges overlap and their diagnostic characters are poorly defined (for details see Bergmans 1988).

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂ ♂ with epaulettes; three upper and five lower cheekteeth:

Epomophorus grandis. Smaller (Table 12, p. 236). Palatal ridges 2–4 divided by medial gap.

E. anselli. Fifth palatal ridge postdental in ♂ ♂, partly interdental in ♀ ♀. On average smaller (Table 12).

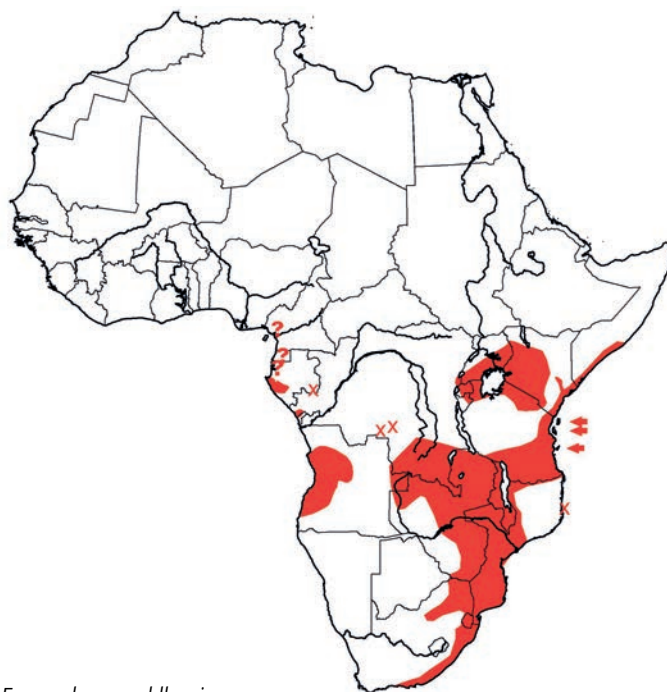

Epomophorus (5 other spp.). Two thick postdental palatal ridges.

Epomops (3 spp.). Three or five thick palatal ridges.

Micropteropus (2 spp.). Smaller (FA: 46–64 mm). Palatal ridges 2–4 divided by medial gap.

Nanonycteris veldkampii. Much smaller (FA: 46–54 mm).

Distribution Endemic to Africa. Mainly found in the Zambezan Woodland BZ, Eastern Rainforest–Savanna Mosaic, Coastal Forest Mosaic BZ and Somalia–Masai Bushland BZ. Recorded from Gabon (and perhaps Cameroon and Equatorial Guinea) to Somalia, and

Epomophorus wahlbergi

southwards to Angola in the west and South Africa in the east. Also Mafia I. (Kock & Stanley 2009), Pemba I. and Zanzibar I. (Bergmans 1988). The distribution is disjunct, partly for ecological reasons, but some gaps, and the apparent absence of records in Mozambique north of the Zambezi R. might reflect insufficient sampling.

Habitat Mainly recorded from woodland savannas (including wetter and drier miombo woodlands and mopane woodland) where fruiting trees are present. Also recorded from fingers of woodland penetrating the rainforest zone, and in mangrove forests and *Acacia–Commiphora* deciduous bushland and thicket. In southern Africa, *E. wahlbergi* is only found in river valleys and on the eastern slopes of mountains – habitats that have a high proportion of evergreen trees, a good water supply, humid conditions and a relatively even climate (Smithers 1983, Volpers & Kumirai 1995). Possibly also found only in similar habitats in the northern part of the range. Ornamental gardens are exploited for food and roosts. In South Africa, *E. wahlbergi* is also found in cities where fig trees have been planted (S. Sowler pers. comm.).

Abundance Uncertain; probably fairly common.

Adaptations Aspect ratio low; wing-loading: no information; flight moderately fast to slow; manoeuvrability moderate. Can turn by banking at very slow speeds (minimum radius <50 cm). Can hover briefly, glide short distances and take off from the ground. Locomotion on ground is clumsy and slow. In contrast, climbing up and down tree-trunks is very competent; forearms move in alternation with thumbs extended to find thumb-holds; strides are long. Climbs along under slender branches, clinging with thumbs and toes and with limbs moving in alternation. Crash-lands on foliage and bunches of fruit, but landing under a ceiling, palm-leaf or branch is accomplished by swooping upwards, hooking the thumbs to the perch with the last wing-stroke, swinging the feet up to grip the perch and then letting go with the thumbs (Wickler & Seibt 1976).

By day, usually hangs in foliage of trees with dense canopies (including evergreen trees in riverine woodlands, ornamental gardens and city parks). Also often hangs from living fronds of palms or the skirts of dead fronds surrounding the stems of *Borassus* palms. Occasionally hangs from thatched ceilings of large open buildings and from eaves of tall buildings. Roost-fidelity varies according to duration of residence in a particular area, and perhaps the safety of the roost. One roost in Kenya was occupied continuously for at least five years and, although the number of individuals at this roost varied from 40 to 100 over this period, group-size usually remained stable for 1–2 weeks at a time. Nomadic individuals perhaps return to familiar roosts in each locality they visit – some roosts have been occupied for several weeks during consecutive years but the individual identity of the occupants was not determined. Some individuals switch between several roosts in one area, for the duration of their stay in that area – possibly to avoid predation or in response to disturbance. Roosting bats hang from one or both feet, with the head either visible or tucked against the belly and covered by the wings. They are motionless for long periods, but may groom, stretch, yawn, or swing intermittently throughout each day; purpose of swinging not known. For details see Wickler & Seibt (1976).

Not known to drink water but *E. wahlbergi* has been seen flying low over water and wetting the ventral pelage (S. Sowler pers. comm.). The kidneys (Figure 29a) are adapted for excreting copious water from diet while maximally retaining salts and other solutes (Happold & Happold 1988). Adaptations enabling the lungs to extract the large amount of oxygen needed for flight include relatively large lungs, extensive alveolar surface area, a thin blood–gas barrier and a high capacity for diffusing oxygen through the body (Maina 1982, Maina *et al.* 1982, in Acharya 1992).

Foraging and Food Feeds on soft fruits, pollen and nectar. Foraging begins around dusk. Individuals move up to 4 km from roosts to feeding areas (Fenton *et al.* 1985). Nomadic movements occur where abundance of food fluctuates seasonally. Fruit is carried to an often regularly used feeding perch, then chewed slowly while the tongue mashes the fruit against the palate. Large pieces of fruit are held in one foot while bites are taken, and the thumbs are used to manipulate food. Pellets of skin, seeds and fibre are spat out (and can be analysed to reveal the diet). Feeds mainly on figs *Ficus* and the soft pulpy ripe fruits, pollen and nectar of trees and shrubs, including species of *Diospyrus*, *Anacardium*, *Terminalia*, *Uapaca*, *Voacanga*, *Tabernaemontana*, *Eugenia*, *Bridelia*, *Euclea*, *Annona*, *Sclerocarya*, *Podocarpus*, *Syzygium*, *Adansonia*, *Sideroxylon*, *Mimusops* and at least eight other genera (Mickleburgh *et al.* 1992, Taylor 2000). Figs sometimes comprise most of the diet. Also eats cultivated fruits but usually when too ripe to have commercial value. Pollinates baobabs *Adansonia* (Kock 1972) and probably other trees including *Parinari*. Chews leaves of *Balanites*, and swallows the juice possibly to obtain steroidal sapagenins (from which steroidal hormones are synthesized) and proteins (Wickler & Seibt 1976). Remains of beetles and other insects have been found in stomach contents (Pienaar *et al.* 1980), but although protein may be obtained in this way, this insectivory might be accidental.

Social and Reproductive Behaviour Usually roosts in mixed-sex groups throughout the year; group-size three to over 100, sex ratio ca. equal in large or very large groups but individual ♂♂ may roost with up to three adult ♀♀ and young. Rarely found roosting singly or in pairs. Sometimes roosts with *E. crypturus*. In Kenya, a detailed study of social interactions in a colony of 40–100 individuals was made during Jan each year, for five years (Wickler & Seibt 1976). The bats return to their roosts at dawn, and most social interactions at the roost occur at this time. These include nose-to-nose sniffing (and occasionally nose-licking), probably to allow group-members to recognize each other. Group-members clump together, but maintain a mean \pm S.D. distance of 16.5 ± 4 cm between neighbours. Individuals strike out with their clawed thumbs if approached too closely, and may half-open the wings, screech and occasionally bite. Mutual-grooming has not been seen, nor any other interactions between roosting adults. In Jan, the bats left precisely between 18:50h and 19:00h, and did not return until ca. 05:30h next morning. They departed one by one and often in different directions. Aggregations occurred at fruiting trees, but it is not known if these were comprised of individuals that roosted together. Elsewhere, bats of this species are reported to leave their day-roosts for 1–2 h and then return (Kirk in Eisentraut 1945).

Courting ♂♂ fly from the roost to perches, 2–20 m above ground, in nearby trees. There, they inflate their cheeks and make a moderately loud gong-like honk repeated at intervals of ca. one second. The epaulettes are displayed, and the wings are half opened, quiver constantly and beat once or twice with each call. Species-specific differences between the calls of sympatric *E. wahlbergi* and *E. crypturus* have been documented (Volpers & Kumirai 1995). The vocalizations and wing-beating displays of *Epomops franqueti* and *Hypsignathus* are substantially different to those of *E. wahlbergi* (see profiles). Rival *E. wahlbergi* ♂♂ are usually separated by at least 50 m. When approached by ♀♀, the ♂♂ double their call repetition-rates and turn towards the approaching ♀. The approaching ♀ hovers for nose-to-nose contact, and often utters a series of soft calls, each call being uttered in the interval between consecutive calls made by the ♂ (sonograms in Wickler & Seibt 1976). Males usually call from one perch for 15 min to over one hour, then move to other perches. Individuals apparently have several preferred perches to which they return on consecutive nights. These observations indicate that *E. wahlbergi* does not have a lek mating-system of any kind (for definitions, see order Chiroptera).

Parturition takes place at the roost in the presence of both male and female group-members (Wickler & Seibt 1976). Females deliver in the normal hanging posture but with the wings folded loosely. The neonate immediately clings to the mother, using the well-developed claws of its thumbs and toes and also its milk-teeth, which are hooked to facilitate gripping the mother's nipples. The placenta is chewed within five minutes of its appearance. The mother licks her vulva, and extensively licks her neonate. During the first 30 minutes, the neonate is placed horizontally across its mother's chest, and is turned (or turns itself) around several times so that its head is at one or other of the nipples. Older juveniles either cling horizontally or vertically with the head upwards. At first, the neonate is carried (attached to nipples and fur) while the mother forages. When volant, the young follow their mothers and maintain contact by calling to each other: the mother's calls are soft honks, the juvenile's are sparrow-like 'tweets' (M. Happold pers. obs.).

Reproduction and Population Structure Litter-size: one, rarely two. In tropical localities, the reproductive chronology appears to be aseasonal polyoestry (or possibly seasonal bimodal polyoestry in some localities [e.g. see Bergmans 1979]), but conclusive year-round data are not yet available. Furthermore, proof of polyoestry appears limited to the record of 2 of 5 ♀♀ simultaneously pregnant and post-lactating in Jan at ca. 15°S in Malawi, and the percentage of ♀♀ that breed more than once/year is not known (Happold & Happold 1990a). At 02°18'S (Masalani, inland Kenya), where *E. wahlbergi* was present throughout year but at low density in Jul–Sep, pregnant ♀♀, lactating ♀♀ and volant young were present continuously from Nov to Apr; polyoestry was proposed (O'Shea & Vaughan 1980) but without published evidence. On the Kenyan coast, lactating ♀♀ were observed in Apr and Oct (A. N. McWilliam in Thomas & Marshall 1984). At 03°54'S (Kikambala, Kenya), parturition occurs in Jan (observations for Jan only with no year-round data [Wickler & Seibt 1976]) and the interpretation that

this indicates seasonal monoestry (Bernard & Cumming 1997) was a mistake. Anciaux de Faveaux (1983) pooled data from different localities, and his conclusion that the species exemplifies bimodal polyoestry or possibly 'continuous polyoestry' (sic) in Shaba (DR Congo) and Rwanda is not justified and needs confirmation.

In South Africa, the majority of ♀♀ are aseasonally monoestrous but a few are polyoestrous. At 28°57'S (Mtunzini, KwaZulu–Natal), births were recorded throughout the year, with peaks in Jul and Nov–Jan (C. Sapsford in Taylor, P. 1998). At ca. 30°S, copulation, ovulation and fertilization peaked in May–Jul; 83% of all births were in Oct–Jan but there were some births in Feb–Jun and 3 of 83 ♀♀ were both pregnant and lactating in April (i.e. polyoestrous) (Sowler 1983). Females were not in close reproductive synchrony and spermatogenesis was continuous. Gestation 160 days. Females reached sexual maturity in their first year; ♂♂ in their second year.

Predators, Parasites and Diseases Ectoparasites include a bed-bug *Africimex constrictus* (Hemiptera: Cimicidae), bat-flies *Ascoapteron semirasum*, *Brachytarsina alluaudi* (Diptera: Streblidae), and seven species of mites (Acari: Spinturnicidae, Myobiidae, Gastronyssidae, Teinocoptidae) (Anciaux de Faveaux 1984). Lagos bat virus was isolated from specimens from the Durban area, South Africa (Mickleburgh *et al.* 1992).

Conservation IUCN Category: Least Concern.

GENUS *Epomops*

Singing Epauletted Fruit Bats

Epomops Gray, 1870. Cat. Monkeys, Lemurs, Fruit-eating Bats Brit. Mus. p. 126. Type species: *Epomophorus franqueti* Tomes, 1860.

Epomops is a polytypic genus endemic to Africa. Diagnostic characters: white basal ear-patches but no other white markings on the head; epaulettes on shoulders of adult ♂♂; FA: 77–102 mm; muzzle simple; interfemoral membrane well developed and with calcar; three or five thick palatal ridges (and others); usually three upper and

five lower cheekteeth, very occasionally four upper cheekteeth and often only four lower cheekteeth (Table 11, p. 228). Palatal ridges are illustrated in Figure 41. Craniodental characters of a representative of the genus are illustrated in Figure 42, but there are inter-specific variations, especially in the dorsal profile (viewed laterally) of the rostrum (Figure 43).

Epomops currently contains three well-defined species of which two (*E. buettikoferi* and *E. franqueti*) occur mainly in rainforest habitats and appear closely related, and one (*E. dobsonii*) occurs mainly in woodland savannas. *Epomops dobsonii*, however, shows some morphological affinity to *Epomophorus* and Bergmans (1989) questioned its placement in *Epomops* (see profile of *E. dobsonii*).

The social behaviour of *Epomops* spp. is very interesting. *Epomops franqueti* and *E. buettikoferi*, which mainly occur in the Rainforest BZ, exemplify an exploded lek mating system (*sensu* Bradbury 1981), which appears to be an intermediate stage in the evolution of classical lekking (see order Chiroptera). The mating system of the less common, savanna species, *E. dobsonii*, is not known but, based on factors that appear to have brought about the evolution of classical lekking (reviewed by Bradbury 1981), its mating system is not likely to be exploded lekking, and even less likely to be classical lekking. If so, this would add to the differences between *E. dobsonii* and the other species of *Epomops*. During courtship, ♂♂ of *E. buettikoferi* and *E. franqueti* perform calling-displays during which they make very loud monotonous 'honks' resembling the ringing of a cracked bell. These are intermediate in loudness between the extremely loud 'honks' of *Hypsognathus* and the quieter 'pings' of *Epomophorus*, but they are loud enough for these species to be regarded as nocturnal pests. In *E. franqueti*, the larynx is enlarged and ossified, larger in ♂♂ than in ♀♀, and located partly in the thoracic cavity and partly in the neck (no data for other species). There is no equivalent information for *E. dobsonii*.

The genus was reviewed by Bergmans (1989). *Epomops* was placed in the *Epomophorus* section of Andersen (1912a), and in the subfamily

Epomops franqueti male.

Figure 41. Palatal ridges of (a) *Epomops buettikoferi* (based on Bergmans 1997 with permission of the author), (b) *E. dobsonii* (based on Bergmans 1997 and Andersen 1912a) and (c) *E. franqueti* (based on Happold 1987).

Figure 42. Skull of *Epomops franqueti* (ZFMK 69.580, adult ♂).

Figure 43. Rostral profiles of *Epomops* spp. showing (a) the convex dorsal profile and relatively long rostrum typical of *E. dobsonii* (BMNH 66.5402, ♂), (b) the slightly convex dorsal profile and relatively long rostrum of some *E. buettikoferi* (BMNH 77.327, ♂) (dorsal profile straight in some specimens) and (c) the straight dorsal profile and relatively short rostrum of some *E. franqueti* (BMNH 68.866, ♂) (dorsal profile slightly concave in some specimens). To emphasize the differences in relative length of the rostrum, the tooththrows are drawn to the same length for each species. Following Bergmans (1989).

Epomophorinae (tribe Epomophorini) of Bergmans (1997). Based on its anatomy, especially that of the larynx, *Epomops* (perhaps excluding *E. dobsonii*) appears to be more closely related to *Hypsignathus* than to *Epomophorus* and the other genera in the Epomophorinae (Andersen 1912a, Bergmans 1989). Chromosomally, based on data from *E. franqueti* and *H. monstrosus*, these genera also seem closely related: the karyotypes of these species cannot be distinguished, but their G- and C-bands differ in two aspects (Haiduk *et al.* 1980, 1981). Phylogenetic relationships between *Epomops*, *Epomophorus* and *Micropteropus* have also been studied by Álvarez *et al.* (1999) and Giannini & Simmons (2003) and, based on genetic data, both studies also indicate a close relationship between these genera. *Hypsignathus* and *E. dobsonii* were not included in these studies.

The species can usually be distinguished by the following characters:

- E. dobsonii*. Five thick and 3–4 thin palatal ridges (Figure 41b).
- E. franqueti*. Three thick palatal ridges; third ridge normally not divided (Figure 41c); West and central Africa between 5°W and 35°E. In area of sympatry with *E. buettikoferi*, usually smaller (FA ♂♂: 83–95 mm, ♀♀ 76–89 mm; GLS ♂♂: 43–51 mm, ♀♀: 37–46 mm).
- E. buettikoferi*. Three thick palatal ridges; third ridge normally divided medially (Figure 41a); West Africa between 14°W and 10°E. In area of sympatry with *E. franqueti*, usually larger (FA ♂♂: 92–103 mm, ♀♀: 82–95 mm; GLS ♂♂: 50–61 mm, ♀♀: 45–53 mm).

Epomops buettikoferi BÜTTIKOFER'S EPAULETTED FRUIT BAT

Fr. Épomophore de Büttikofer; Ger. Büttikofer's Epaulettenflughund

Epomops buettikoferi (Matschie, 1899). Megachiroptera Berlin Mus., p. 45. Schlieffelsville, Junk River, Liberia.

Taxonomy Originally *Epomophorus buettikoferi*. Synonyms: none. Chromosome number: not known.

Description Medium-sized, robustly built fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; three thick palatal ridges of which the third is almost always divided. Males usually darker, larger and heavier than ♀♀. Pelage soft, slightly fluffy; extending half-way along forearm; sparser on throat; mid-dorsal hairs 10–11 mm, shorter ventrally. Dorsal pelage variable, rich chocolate brown to pale golden-brown, tinged with orange or rusty-red on nape and legs; hairs unicoloured. Ventral pelage slightly paler and greyer grading to off-white or white mid-ventrally, or with clearly demarcated white or whitish mid-ventral patch; chin and throat medium brown in ♂♂ but only slightly darker than chest in ♀♀. Adult ♂♂ with a conspicuous white epaulette on each shoulder (retracted within pouch except when displayed); ♀♀

with a small, inconspicuous invagination on each shoulder containing short hairs of same colour as dorsal pelage. Head usually larger and more robust in ♂♂; muzzle long and broad; lips and cheeks fleshy and expansible (especially in ♂♂). Ears brown. Eyes large and brown. Palate with three thick ridges of which 1 and 2 are undivided whereas 3 is almost always divided by wide medial gap, occasionally divided by a narrow gap or very rarely undivided (cf. *E. franqueti*), and five to eight thin, irregularly serrated ridges (Figure 41a; Bergmans 1989). Wing-membranes brown; attaching to second toe. No tail.

Skull, on average, medium-sized for an African fruit bat. Rostrum relatively long for an African fruit bat and for an *Epomops* (rostral length ♂♂: 44–48% of GLS, ♀♀: 41–44% of GLS); dorsal profile (viewed laterally) straight or somewhat convex (Figure 43b; Bergmans 1989). Postdental palate almost flat (cf. *Epomophorus* spp. of similar size). Dental formula usually $2^{121}/_{2132} = 28$ but outer upper incisor sometimes absent.

Geographic Variation No subspecies are recognized. Body and skull dimensions decrease from west to east, specimens being larger west of Ghana and smallest towards E Ghana and in Nigeria (Bergmans 1989). *Epomops franqueti* also increases in size from west to east and therefore these species show their greatest difference in size in their zone of sympatry.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Epomops dobsonii. Five thick palatal ridges. South of Equator.

E. franqueti. Third palatal ridge usually undivided. Comparatively widespread. In sympatric zone, smaller (FA ♂♂: <91 mm, FA ♀♀: <86 mm; GLS ♂♂: <51 mm, GLS ♀♀: usually <45.8 mm), but note that subadult *E. buettikoferi* and adult *E. franqueti* overlap in size and are difficult to distinguish.

Epomophorus (8 spp.). Six thick palatal ridges.

Micropteropus (2 spp.). Smaller (FA: 46–64 mm).

Nanonycteris veldkampii. Smaller (FA: 46–54 mm).

Distribution Endemic to Africa. Known mainly from the Rainforest BZ and Northern Rainforest–Savanna Mosaic (but with some records in the Guinea Savanna BZ), in West Africa. West of the Dahomey Gap, the distribution appears contiguous from Guinea just north-west of the Sierra Leone border to somewhere between the line connecting Kumasi and Takoradi in Ghana and the western border of Togo (Bergmans 1975). There are also some records from Senegal, Guinea-Bissau, Côte d'Ivoire and E Ghana, which appear isolated but might not be so. Not known from Togo or Benin, but 13 specimens taken in Nigeria indicate the existence of a possibly disjunct population east of the Dahomey Gap (Bergmans 1982).

Habitat Appears to be a moist savanna species that penetrates into lowland rainforest. It is most closely associated with patches of disturbed forest, secondary bush, cultivated land, gallery forest and the edges of areas of closed forest (Wolton *et al.* 1982, Bergmans 1988).

Abundance Locally abundant, especially in disturbed forest and along forest edge. More commonly caught in mist-nets set at ground level (0–3 m) than in canopy (>5 m). A year-round resident in Guinea savanna, with numerous recaptures of marked individuals.

Adaptations Males and ♀♀ highly dimorphic, with ♂♂ having a large palpable larynx designed for sound production. Pelvic girdle highly dimorphic. Immature ♂♂ identifiable by nearly closed and palpable pubis anterior to penis. Thumbs relatively short and weak. Clumsy when crawling along branches, so accesses fruits only by flight. Roosts by day well hidden in dense forest, ca. 8 m above ground; details not known.

Foraging and Food Primarily frugivorous. Foraging begins at dusk, distributed evenly throughout the night for ♀♀. Males more active after midnight, when calling dies down (see below). Carries fruit to feeding-roost 50–100 m from fruiting tree. Holds fruit with foot and thumb and fills large cheek-pouches to bulging with pulp. Sucks slowly to ingest only juices and small seeds before spitting out fibre and seed pellet. Feeding-roosts are used for >10 nights if fruit abundant, and accumulate large amounts of fibre pellets. Will visit *Ceiba pentandra* flowers, but is primarily frugivorous. Diet includes 15 genera (13 families; Marshall 1985) but, in Guinea Savanna, diet is dominated by large-fruited *Ficus capensis* and *F. vallis-choudae* (>20 g). In captivity, ingests ca. 150% of body mass and 1350 kJ/kg^{0.75} nightly (Thomas 1984a). In captivity, mean \pm 1 S.D. nightly consumption of food by ♂♂ was 103.7 \pm 14.2 g (n = 7) and by ♀♀ was 145.0 \pm 11.3 g (n = 10); mean consumption per unit body weight was 0.92 g/g^{bwt}; the mean through-put time was 69 \pm 14 min, and the percentage dry weight assimilated was 87% (Wolton *et al.* 1982).

Social and Reproductive Behaviour At night, ♂♂ congregate in great numbers along stretches of rivers to chorus in exploded leks (*sensu* Bradbury 1981) for hours with loud rhythmic 'kyonks'. Rhythm increases periodically from ca. 1/sec to staccato 'ki-kong-ki-kong-kaa-kaa-kaa', apparently as ♀ approaches. Males call year-round, but activity on lek varies seasonally (Thomas & Marshall 1984). During mating periods (Feb–Apr, Aug–Oct), all territories are occupied and calling begins at ca. 19:42h. Outside mating period, few ♂♂ call on bright moonlit nights and they start 90 minutes later. On dark nights, most ♂♂ call, but start 30 minutes later. Calling dies down after midnight, coinciding with increased mist-net captures. Radio-tagged bats roosted solitarily in dense foliage along edge of gallery forest. A report of large colony in Monrovia, Liberia (Kofron & Chapman 1994) is probably erroneous.

Reproduction and Population Structure Litter-size: one (n = ca. 20). In Côte d'Ivoire and Liberia, the reproductive

chronology is continuous bimodal polyoestry with postpartum oestrus. At 06° 13' N (Lamto, Côte d'Ivoire: Savanna in Rainforest–Savanna Mosaic; rain throughout year with peaks in Apr–Jun and Sep, minimal in Dec–Jan), births occur at onset of long wet season and the major increase in availability of fruit (Feb–Mar), and six months later, roughly at onset of short wet season and a minor increase in availability of fruit (Aug–Sep) (Thomas & Marshall 1984). Gestation ca. six months. Lactation (for population as a whole) for ca. 7–8 weeks after the Feb–Mar births, and ca. 13 weeks after the Aug–Sep births – the longer second period possibly due to less synchrony between ♀♀. During second month of lactation, >90% of ♀♀ are palpably pregnant, indicating occurrence of postpartum oestrus. Adult testes length constant throughout the year at 7.6 mm. Juvenile ♂♂ and ♀♀ become volant in May–Jun and Nov–Dec, with similar body mass (45–65 g) and forearm (74–76 mm). Females mature at six months and give birth at 12 months. Males below 140 g have small (<3 mm) or abdominal testes and no epaulettes. Males begin puberty at ca. nine months and by 15 months are indistinguishable from adults. At ca. 6° N (C Liberia; Rainforest BZ; rainfall unimodal, wet season Mar–Nov, dry season Dec–Feb), the reproductive chronology, and dates of events, are the same as at Lamto (Kofron & Chapman 1994).

Predators, Parasites and Diseases Ectoparasites not known (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Epomops dobsonii DOBSON'S EPAULETTED FRUIT BAT

Fr. Épomophore de Dobson; Ger. Dobsons Epaulettenflughund

Epomops dobsonii (Bocage, 1899). J. Sci. Math. Phys. Nat. Lisboa, ser. 2, 1: 1. Quindumbo, Benguela, Angola.

Taxonomy Originally *Epomophorus dobsonii*. Although Bergmans (1989), and also Simmons (2005), retained *dobsonii* in *Epomops*, Bergmans (1989) recognized important characters that make this form distinct from *Epomops* and closer to *Epomophorus*, and he suggested that *dobsonii* is possibly not well placed in *Epomops*. These include the strongly concave interdental palate of *dobsonii*, differences in the palatal ridges and differences in the form of the pterygoid wing of the skull. Synonyms: none. Chromosome number: not known.

Description Small, fawn to grey-brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; and, uniquely, five thick palatal ridges. Males on average larger than ♀♀. Pelage soft, slightly fluffy; extending along each upper arm and half-way along each forearm; mid-dorsal hairs ca. 13 mm. Dorsal pelage pale yellowish-brown to greyish-brown; some individuals with a bleached appearance; hairs pale brown with greyish-brown at base and fawn to greyish-brown at tip. Ventral pelage pale cinnamon-brown suffused with grey, pale brown or creamy-brown; usually palest on throat and belly; ♂♂ with chest distinctly darker greyish-brown. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed); adult ♀♀ apparently without shoulder pouches (n = 5). Head dog-like;

larger and more robust in ♂♂. Muzzle long and broad. Lips fleshy and moderately expansible. Ears dark brown. Eyes large. Palate with three thick interdental ridges, two thick, postdental ridges, each with two triangular projections, and three or four thin ridges (Figure 41b). Wing-membranes dark brown; attaching to second toe. Tail very short or absent.

Skull medium-sized for an African fruit bat. Rostrum relatively long for this family and for an *Epomops* (rostral length ♂♂: 46–47% of GLS, ♀♀: 43–45% of GLS); dorsal profile (viewed laterally) convex (Figure 43a) (Bergmans 1989). Postdental palate almost flat (cf. *Epomophorus* spp. of similar size). Dental formula usually $^{2121}/_{2132} = 28$.

Geographic Variation Data too limited to be conclusive.

Similar Species Thirteen other fruit bats have simple muzzles; basal ear-patches but no other markings on head; three upper and five lower cheekteeth:

Epomops franqueti and *E. buettikoferi*. Three thick palatal ridges.

Epomophorus (8 spp.). Six thick palatal ridges.

Micropteropus (2 spp.). Smaller (FA: 46–64 mm).

Nanonycteris veldkampii. Smaller (FA: 46–54 mm).

Distribution Endemic to Africa. Widespread across the Zambezian Woodland BZ between 8 and 18°S, from Angola to Tanzania and Malawi (Bergmans 1989). Outlying records north of 8°S in Tanzania and Rwanda (Bergmans 1989) are currently considered questionable (W. Bergmans pers. comm.). Predicted to occur east of L. Malawi.

Habitat Mainly wetter miombo woodland and mosaics of the above with adjacent types of vegetation. Also afro-montane vegetation at 1890 m at Kibweli, Tanzania, and (if this dubious record proves valid) the mosaic of East African evergreen bushland and secondary *Acacia* wooded grassland at Rubona, Rwanda. Bergmans (1989) expects *E. dobsonii* to occur in miombo woodland bordering the eastern side of L. Malawi and in the tongue of this vegetation extending northwards to L. Victoria. The distribution appears restricted by the belts of shrublands and desert vegetation lining the Atlantic coast in the west, by rainforest in the north and by drier vegetation in the south, south-east and east.

Abundance Moderately rare in collections, but occurs in poorly surveyed areas and is perhaps more common than the records indicate (see also below).

Remarks Litter-size: one or commonly two according to Hill & Smith (1984) but the exact frequency of occurrence of twins is not known. Three ♀♀ caught at Mt Soque in Angola at end of Aug were either pregnant or lactating (Mickleburgh *et al.* 1992). Apparently there is no other information about the biology of this species. There is as yet no evidence that *E. dobsonii* has an exploded lek mating system (cf. *E. buettikoferi* and *E. franqueti*); unlike these species, it has not been reported to be a nocturnal pest because of the noise made by aggregations of displaying ♂♂. Also, Bradbury (1981) suggests that lekking is most likely to evolve in species that are common because territoriality and female-defence become increasingly less viable as population density increases. It would be most interesting to know if *E. dobsonii* is really as uncommon as it appears to be, and if it exemplifies a mating system very different to that of the other two species of *Epomops*. Possibly lekking and exploded lekking are more suited to rainforest habitats than to savannas. Lagos bat virus has been isolated from *E. dobsonii* (Calisher *et al.* 2006).

Conservation IUCN Category: Least Concern.

Epomops franqueti FRANQUET'S EPAULETTED FRUIT BAT

Fr. Épomophore de Franquet; Ger. Franquets Epaulettenflughund

Epomops franqueti (Tomes, 1860). Proc. Zool. Soc., Lond. 1860: 54. Gabon.

Taxonomy Originally *Epomophorus franqueti*. Synonyms: *comptus*, *streptitans*. Subspecies: none recognized by Bergmans (1989) but see Geographic Variation. Apparently closely related to *Epomops*

buettikoferi. Chromosome number (Cameroon): 2n = 36; aFN = 66 (Haiduk *et al.* 1981); (Gabon): 2n = 35; aFN = 66 (Primus *et al.* 2006).

Description Small to medium-sized, fawn to reddish-brown fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; three thick palatal ridges, which are usually undivided. Males and ♀♀ similar in colour; ♂♂ on average larger than ♀♀. Pelage soft, slightly fluffy, extending along each upper arm and half-way along each forearm; mid-dorsal hairs ca. 8 mm. Dorsal pelage fawn, pale brown or medium to dark reddish-brown; hairs unicoloured. Shoulders and nape sometimes greyish-brown. Ventral pelage pale brown often merging into white on abdomen and chest. Adult ♂♂ with white epaulette on each shoulder (retracted within pouch except when displayed); ♀♀ with a small, inconspicuous invagination on each shoulder containing pale brown hairs ca. 12 mm long. Head dog-like; larger and more robust in ♂♂. Muzzle moderately long and broad; lips and cheeks fleshy and expansible (especially in ♂♂). Ears dark brown. Eyes large. Palate with three thick ridges (1–2 undivided, 3 usually undivided [cf. *E. buettikoferi*]), and 5–8 thin, narrowly divided, finely serrated ridges (Figure 41c). Wing-membranes medium to dark brown; attaching to second toe. Tail very short or absent.

Skull (Figure 42) medium-sized for an African fruit bat. Rostrum of medium relative length for this family but short for an *Epomops* (rostral length ♂♂: 39–43% of GLS, ♀♀: 37–40% of GLS); dorsal profile (viewed laterally) slightly concave or straight, very rarely slightly convex (Figure 43c) (Bergmans 1989). Postdental palate almost flat (cf. *Epomophorus* spp. of similar size). Dental formula usually $2^{121}/_{2132} = 28$ but outer upper incisor often absent.

Geographic Variation A western subspecies (*E. f. strepitans*) was described by Andersen (1912a) but Bergmans (1989) was unable to delimit subspecific ranges and predicted that the species has a continuous distribution with clinal increase in body and skull dimensions from west to east: e.g. in West Africa (Ghana and Côte d'Ivoire), FA (♂♂): 87.6 (83.5–93.9) mm, n = 74, FA (♀♀): 81.6 (76.5–87.1) mm, n = 78; GLS (♂♂): 46.8 (43.3–49.9) mm, n = 73, GLS (♀♀): 41.9 (37.8–45.3) mm, n = 71; in central Africa (Gabon to Uganda), FA (♂♂): 95.6 (89.9–100.9) mm, n = 51, FA (♀♀): 89.3 (84.2–93.8) mm, n = 53; GLS (♂♂): 50.7 (47.4–52.4) mm, n = 39, GLS (♀♀): 45.2 (42.6–47.8) mm, n = 43 (data derived from Bergmans 1989). In contrast, *E. buettikoferi* decreases in size from west to east so these species show their greatest difference in size in their zone of sympatry.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; three upper and five lower cheekteeth:

Epomops dobsonii. Five thick palatal ridges.

E. buettikoferi. Third palatal ridge usually divided. West Africa only, between 14°W and 10°E. In sympatric zone, larger (FA ♂♂: 92–102 mm, FA ♀♀: 89–96 mm; GLS ♂♂: 53.8–60.2 mm, GLS ♀♀: 45.8–56.6 mm). Note: *E. franqueti* from further east tend to be larger on average than those from the sympatric zone.

Epomophorus (8 spp.). Six thick palatal ridges.

Micropteropus (2 spp.). Smaller (FA: 46–64 mm).

Nanonycteris veldkampii. Smaller (FA: 46–54 mm).

Epomops franqueti

Distribution Widespread in the Rainforest BZ and Rainforest–Savanna Mosaics with very marginal extensions into the Guinea Savanna BZ and Zambezian Woodland BZ. Recorded from Côte d'Ivoire to L. Victoria and southwards to Angola and S DR Congo. Previous reports from Guinea are erroneous (J. Fahr, in Simmons 2005). Map based on Bergmans (1989).

Habitat Mainly recorded from wetter and drier types of lowland rainforest, but also recorded from afromontane vegetation and mosaics of rainforest with woodland and grassland, and occasionally from *Isoberlinia* woodland and wetter miombo woodland (Bergmans 1989). In the Guinea Savanna and Zambezian Woodland BZs, they probably reside in relict and riverine forests. In Gabon, various types of secondary forest are preferred to primary forest, and hence the habitat is patchy mosaic (Bradbury 1981). Often caught in clearings close to dense undergrowth, and in gardens.

Abundance Common in Nigeria (Happold 1987), Gabon (Brosset 1966) and DR Congo (Lang & Chapin 1917b). Probably fairly common in the Rainforest BZ, but abundance apparently varies with seasonal changes in abundance of fruit and flowers, at least in some areas.

Adaptations Aspect ratio low; wing-loading very high. Flight slow and manoeuvrable. Commonly flies through the canopy and close to the ground (Jones 1972). Can take off from the ground (Brosset 1966). Lands neatly without crashing into vegetation. Roosts in dense foliage of large trees such as *Terminalia*, hanging freely from small branches usually 4–6 m above ground. Sometimes roosts in low bushes. Often roosts near or over water. Monthly home-ranges for five ♀♀ in Gabon ranged from 1.2 to 1.6 km in diameter (Bradbury 1981). Based on differences in foraging strategies, ♂♂ are likely to have much larger home-ranges. When individuals were exposed to decreased ambient temperatures, their body temperatures declined

generally in accordance with ambient temperature: the T_A averaged mostly 10 °C greater than the T_B (cf. *Eidolon helvum*, *Micropteropus pusillus*) (Jones 1972).

Foraging and Food Frugivorous. Sometimes congregates in large numbers at particular sources of food. Takes fruits from canopies of trees and also collects fallen fruits from the ground (Brosset 1966). Whole fruits, or large pieces, are often engulfed in the lips and carried to a perch 200 m or more away. At the perch, food is held by a hindfoot, the mouth, wrists or in the pocket formed by the wing-membrane when a wrist is flexed. Thumbs are rarely used to hold food, but individuals often hold onto a branch or leaf with one thumb and one hindfoot while feeding. Lips and tongue squeeze and suck out the juice, which is swallowed; pulp and seeds discarded. This species helps to disperse seeds but is not known to assist in pollination. In Equatorial Guinea (Rio Muni), based on direct observations and also captures in mist-nets set 0–2 m and 4–6 m above ground, Jones (1972) noted that *E. franqueti* forages and roosts in the same habitat, and at the same time, as *Eidolon helvum* and *Micropteropus pusillus*, but competition is reduced because the species for the most part utilize different strata – of the netted fruit bats, 100% of *Eidolon*, 73% of *Epomops* and only 10% of *Micropteropus* were caught in the higher nets.

As in *Hypsignathus monstrosus*, the foraging strategies and diets of ♂♂ and ♀♀ are different (Bradbury 1981). In Gabon, 36% of the diet of ♀♀ is fruits of *Solanum torvum*, which produces fruit throughout the year but only 1–2% of fruits are ripe on any one night and the quality of this food is comparatively poor. Females fly to the same locations on consecutive nights, take a few fruits from each plant and then move on to other plants. Twenty-one per cent of the diet is figs from *Ficus* spp., which are hard to locate and produce fruit for only 5–10 days at intervals of 1–3 years, but fruiting trees produce abundant figs of high quality. The remaining 43% of the diet is *Musanga*, guavas and bananas. In contrast, for ♂♂, figs comprise a much larger fraction of the diet. For implications of these differences, see Bradbury (1981) and profile of *Hypsignathus monstrosus*. In Equatorial Guinea, *E. franqueti* has been seen most frequently feeding on fruits of *Terminalia*, but it also ate fruits of *Artocarpus*, *Annona* and mangoes (Jones 1972). It also eats fruits of *Persea* and *Cecropia*, and captive bats eat plantains and avocados (Bradbury 1981, Mickleburgh *et al.* 1992).

Social and Reproductive Behaviour Usually roosts singly, very occasionally in twos, rarely in threes (Rosevear 1965, Jones 1972). Captive individuals roost as far from each other as possible (Jones 1972). *Epomops franqueti* has an exploded lek mating system (*sensu* Bradbury 1981). In Gabon, ♂♂ typically hold territories ca. 200 m or more in diameter. These are large enough to contain significant amounts of resources required by ♀♀, but the ♂♂ also place their territories over sites in which roosting ♀♀ and food resources are scarce or absent (Bradbury 1981). These territories are clustered (not uniformly dispersed as in resource-based territories). Adult ♂♂ display within their territories and the territories are presumably selected not for their resources but for qualities that optimize the effectiveness of the displays while minimizing opportunities for predation. The territories are, in some ways, similar to the sites within classical leks from which male *Hypsignathus* display (see profile). However, the territories of *E. franqueti* are very much

larger and are not as tightly clustered as sites held by ♂♂ within classical leks. For this reason, they are known as exploded leks. In Gabon, the gaps between exploded leks range from 2 to 4 km. While displaying, ♂♂ beat their half-open wings, display their epaulettes and make a loud metallic ‘honk’ at intervals of a second or less. At a distance, this very distinctive call sounds like a cracked bell; close to, it has been described as ‘kurnk’ or ‘kyurnk’ (Lang & Chapin 1917b). Calling-displays occur throughout the night. The call repetition-rate usually increases rapidly just before calling ceases.

Reproduction and Population Structure Litter-size: one. In equatorial Uganda, the reproductive chronology is continuous bimodal polyoestry with postpartum oestrus (Okia 1974b). Gestation 5–6 months. Females are in reproductive synchrony; births occur in Mar and Sep. Young probably not weaned until a few weeks before the next birth. The presence of lactating ♀♀ in almost all months may have misled earlier observers into thinking reproduction was aseasonal. In S Congo, seasonal bimodal polyoestry, with births in Feb and Sep, was proposed by Bergmans (1979) but without corroborative evidence.

Predators, Parasites and Diseases Ectoparasites include a bat-fly *Basilia tenuispina* (Diptera: Nycteribiidae) and a mite *Teinocoptes epomophori* (Acari: Teinocoptidae) (Anciaux de Faveaux 1984). Rift Valley fever virus been isolated from *E. franqueti* (Addy *et al.* 1978).

Conservation IUCN Category: Least Concern.

GENUS *Hypsignathus*

Hammer-headed Fruit Bat

Hypsignathus H. Allen, 1861. Proc. Acad. Nat. Sci. Philadelphia, p. 156. Type species: *Hypsignathus monstrosus* H. Allen, 1861.

Hypsignathus is a monotypic genus endemic to Africa. Diagnostic characters: white basal ear-patches (sometimes inconspicuous) but no other white markings on the head; FA: >112 mm; head with humped nose and truncated muzzle, which ends in a fleshy plate; usually three upper and five lower cheekteeth (very occasionally four upper cheekteeth) (Table 11, p. 228). Palatal ridges as in Figure 44. The single species is the largest bat on the African mainland, and shows more sexual dimorphism than any other bat in the world (Figure 44). The genus is based mainly on the extraordinary anatomy of the skull (Figure 44), lips, dentition, vocal chords and air-sacs of the ♂ (see species profile). These characters are associated with the production of such extremely loud vocalizations that this species is sometimes considered to be one of Africa's greatest nocturnal pests. The vocalizations are part of courtship displays carried out by ♂♂ at traditional sites referred to as classical leks (see species profile); no other African bat is known to have a classical lek mating system although two species of *Epomops* have an exploded lek mating system, which has some of the characteristics of classical lekking and may represent an intermediate stage in the evolution of classical

Hypsignathus monstrosus
male.

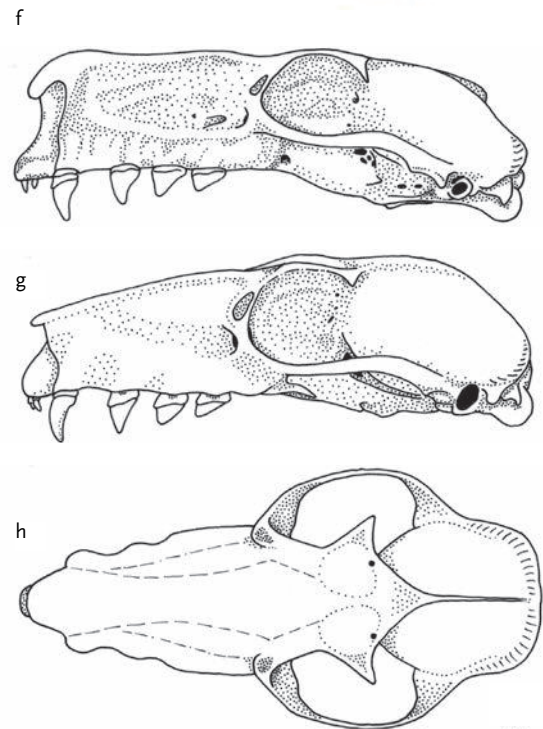

Figure 44. *Hypsignathus monstrosus*. Lateral views of head of (a) adult ♀ and (b) adult ♂. (c) and (d) Frontal views of ♂ head. The latter shows the mobile carunculated flanges surrounding the sound amplifying lips, here constricted around extruded spatulate tongue. (e) Palatal ridges (from photo in Bergmans 1989). (f) Lateral view of skull of adult ♂ (BMNH 98.10.7.2). (g) Lateral view of skull of adult ♀ (RMCA 93-079-M-0367). (h) Dorsal view of skull of adult ♂ (BMNH 98.10.7.2).

lekking (Bradbury 1981). Based on its anatomy, especially that of the larynx, *Hypsignathus* appears to be more closely related to *Epomops* than to *Epomophorus* and other genera (Andersen 1912a, Bergmans 1989). However, von Zeller (1984) discusses differences in the topography of the thoracic organs of *Hypsignathus* and *Epomops*, which suggest that the enlargement of the larynx took place independently in the phylogeny of both genera. The karyotypes of *Hypsignathus* and *Epomops franqueti* cannot be distinguished, but their G- and C-bands differ in two aspects (Haiduk *et al.* 1980, 1981). Males have the unusual sex chromosome combination of XO instead of XY (Bogart *et al.* 1977).

Hypsignathus monstrosus HAMMER-HEADED FRUIT BAT

Fr. *Hypsignathe monstrueux*; Ger. Hammerkopf-Flughund

Hypsignathus monstrosus H. Allen, 1861. Proc. Acad. Nat. Sci. Phil., p. 156. Gabon.

Taxonomy Synonyms: *labrosus*, *macrocephalus*. Subspecies: none. Chromosome number (DR Congo, Gabon): $2n = 36$; $aFN = 68$ (Haiduk *et al.* 1980, Primus *et al.* 2006).

Description Large, dark brown fruit bat with pale, woolly mantle; anterior and posterior white basal ear-patches, which are sometimes inconspicuous, but no other white markings on head; no epaulettes; easily recognized by its size and uniquely hammer-shaped head (Figure 44). The largest of all bats on the mainland of Africa. Males and ♀♀ similar in colour; ♂♂ almost twice as heavy as ♀♀, usually larger, and morphologically very different. Pelage soft, extending dorsally along each upper arm and for some distance along each forearm; mid-dorsal hairs ca. 13 mm. Dorsal pelage sepia brown (sometimes suffused with pale greyish-brown) becoming rusty-brown on rump and legs; hairs unicoloured or with pale greyish-brown at tip. Shoulders and neck with mantle of longer, woollier, pale greyish-brown pelage. Ventral pelage slightly paler than dorsal pelage with a whitish collar joining the mantle. Head (especially in ♂♂) large with greatly expanded, humped muzzle, which, instead of tapering, ends bluntly in a flat, fleshy plate formed by the upper and lower lips (see Adaptations). Females with considerably less monstrous heads! Ears blackish-brown, triangular. Eyes very large. Palate with three thick ridges that have wide extremities and narrower centres, a fourth, partly postdental, weakly serrated ridge, which has a wide, cushion-like pad near each extremity and a shallow, concave middle, a fifth ridge, which is similar to the fourth but more strongly serrated and less shallow in the middle, and five or six thin, serrated, irregular ridges, which are sometimes divided (Figure 44c). Tongue with expanded tip (Figure 35a). Wings blackish-brown with woolly brown dorsal pelage extending along the forearm and a strip of whitish pelage on the ventral surface; wing-membranes attaching to second toe. No tail. For further information, see Langevin & Barclay (1990).

Skull (Figure 44) larger and more robust than in any other African fruit bat. Rostrum massive, relatively long, very deep but laterally compressed, especially in ♂♂. Basicranial axis markedly deflected. Interdental palate concave from side to side and from front to back, but postdental palate lacks the raised sides. Dental formula usually $^{2121}/_{2132} = 28$ but an extra upper premolar (P^1) is present very occasionally. Inner ridges of posterior upper premolar, upper molar, posterior lower premolar and lower molars are much more

Hypsignathus was placed in the *Epomophorus* section of Andersen (1912a) and in the subfamily Epomophorinae (tribe Epomophorini) of Bergmans (1997). Apparently, the phylogenetic relationships between *Hypsignathus* and other genera of fruit bats have not yet been investigated using genetic data. Morphology suggests affinities with typical *Epomops* (Andersen 1912a).

The single species is *Hypsignathus monstrosus*.

Meredith Happold

developed than in *Epomophorus*, and the median furrows of these teeth are correspondingly deepened.

Geographic Variation None recorded.

Similar Species None.

Distribution Endemic to Africa. Found throughout most of the Rainforest BZ and some distance into the surrounding Rainforest–Savanna Mosaics. Also a few records in the Guinea Savanna, Zambezian Woodland and Afromontane–Afroalpine BZs. Recorded from Sierra Leone to W Kenya, and south-westwards to NW Angola. Map based on Bergmans (1989).

Habitat Wetter and drier types of lowland rainforest, swamp forest and mosaics of these forests with secondary grasslands (Bergmans 1989). Records outside the rainforest zone are uncommon, but

Hypsignathus monstrosus

riverine forests appear to serve as passageways into woodland savannas such as *Isoberlinia* woodland to the north and miombo woodland to the south (Bergmans 1989). Relict forests and afromontane vegetation are also inhabited and there are some records from palm forests and a mangrove swamp. The rare records from savanna habitats are perhaps those of vagrants. Not recorded above 1800 m.

Abundance Said to be common in the Rainforest BZ, although local abundance is probably determined by the availability of ripe fruit. Rare outside the rainforest.

Adaptations Aspect ratio low; wing-loading exceptionally high (Norberg & Rayner 1987), but this needs confirmation. Flies directly up to 10 km at a time to find food, but can also manoeuvre and hover moderately well. Cannot take off from the ground. Typically roosts by day in the forest canopy 20–30 m above ground. Hangs from exposed branches beneath an umbrella of dense foliage, and shows no preference for particular species of trees. Also recorded roosting in undergrowth (Lang & Chapin 1917b), a cave (Nowak 1999, but not confirmed), among rocks (Sanderson 1939) and in a hut (Van Deusen 1968), but these roosts are probably unusual. Roost-fidelity is low (Bradbury 1977). Individuals typically change roosts after 5–9 days; some stay in one area and move only 50–100 m from one roost to the next while others move 1–10 km away. The marked sexual dimorphism and peculiar morphology of the head in ♂♂ is associated with the production of calls that attract ♀♀ (see Social and Reproductive Behaviour). These calls – extremely loud monotonous honking – are produced in a greatly enlarged larynx and amplified by resonating chambers. The larynx is one-half the length of the vertebral column and fills most of the thoracic cavity. The resonating chambers are a pair of inflatable pharyngeal air-sacs that open into a large sinus in the humped muzzle, and the gaping mouth, which has expansible cheeks and widely flaring lips (Lang & Chapin 1917b, von Zeller 1984). The tongue is large and powerful, with backward-pointing papillae; used for rasping fruit so juice can be extracted. The stomach and intestines are long and narrow with many folds in the interior wall to facilitate digestion of fruit. A captive individual drank regularly by flying low and scooping water into its mouth.

Foraging and Food Feeds mainly on the fruits of trees in forests, secondary growth and old plantations. Forages mainly in the canopy, but commuting may be above the canopy or as low as 1–4 m above the ground. There are two foraging strategies (Bradbury 1977, 1979, 1981). Females, subadults and non-displaying adult ♂♂ forage along regular routes and exploit dependable sources of food – the fruits of *Anthocleista* trees – although these are not of the highest quality. These trees grow in monospecific stands well known to the bats and, during each mating season of *H. monstrosus*, they bear thousands of fruits of which less than 1% are ripe and maximally nutritious at any one time. In contrast, sexually active ♂♂ fly from their roost to their leks (see below) where they display for 3–4 hours before flying directly to, or in search of, sources of particularly high-quality food such as figs *Ficus* spp. Fig trees bear small crops for ca. 10 days, do not fruit again for 6–24 months, and are randomly distributed in the forest. They are hard to find but, once located, provide a substantial supply of high-quality food for several days. They are usually ca. 7 km

away but may be up to 10 km away. Many sexually active ♂♂ forage until dawn and then return to their roosts: others return to the lek.

Diet: includes the fruits of *Ceiba*, *Musanga*, *Chlorophora*, *Solanum*, *Adenia* and especially figs *Ficus* and fruits of *Anthocleista*, and also bananas, guavas, mangoes and soursops (Lang & Chapin 1917b, Rosevear 1965, Bradbury 1977, Fujita & Tuttle 1991 and Thomas 1982 in Mickleburgh *et al.* 1992). Faeces usually contain seeds, suggesting that these bats play an important role in the dispersal of rainforest trees. Observed to attack chickens (one bat collected; identity confirmed), and to eat scraps of meat and the skinned carcasses of small birds that a museum collector frequently left lying on the ground in a well-lit area outside his house in Gabon (Van Deusen 1968). A bat would hover briefly over the carcass, reach down and seize it in the mouth, and carry it off. One individual, which regularly roosted during the day in a nearby hut, carried carcasses to this roost during the night and ate them there. It is not known if *H. monstrosus* regularly eats meat, but the observer suggests that birds that roost in the open in rainforests could provide a readily available source of food for this fruit bat.

Social and Reproductive Behaviour Bradbury (1977) conducted an outstanding study of the behaviour of *H. monstrosus* in NE Gabon. Both ♂♂ and ♀♀ very often roost singly. Groups are usually small (4.4 ± 2) but sometimes include up to 25 individuals, and at any particular roost, group-size is extremely labile. Groups can include one or both sexes and all age-classes, and apparently group-composition is also labile. A distance of 10–15 cm is maintained between roosting bats (except for ♀♀ with young), and ♂♂ often roost at the periphery of the group. Behaviour at roosts is minimal. The bats often defecate early in the day, then rest or sleep until dusk. They do not vocalize, groom each other or squabble over positions, and ♂♂ do not approach the ♀♀. At sunset, all of the bats groom themselves and then leave quietly and independently to forage or visit a lek.

There are two breeding seasons per year, with mating occurring in two periods of 1–3 months' duration. During these periods, aggregations of 20–135 ♂♂ gather in trees along rivers and streams, in special arenas (leks) that are usually ca. 40 m wide and 400–1600 m long. Males compete aggressively for display-territories (ca. 10 m in diameter) within these arenas, and then carry out a display of honking and wing-beating, which attracts ♀♀. Females fly along the arena, choose a ♂ and may land beside him. If this happens, the ♂ makes a 'staccato-buzz' call and may copulate immediately. The ♀ then departs and the ♂ resumes his display. This behaviour meets the specifications of a mating-system referred to as classical lekking, which is defined by the following criteria. (1) Males do not participate in parental care. (2) Males aggregate in particular areas (leks) and establish display-territories there, which are very much smaller than their home-ranges. (3) Display-territories contain no resources for ♀♀ other than access to a ♂. (4) Females have the opportunity to select a ♂ to mate with, and all matings occur at the lek. Lekking (which occurs in some birds and some other mammals) is often associated with 'secondary' features, and these also occur in *H. monstrosus*. (a) There is marked sexual dimorphism. (b) Males mature much later than ♀♀ (18 months versus six months). (c) Lek-locations are traditional. (d) Displays are extremely ritualized. (e) The mating success of ♂♂ in any one lek is highly skewed (in *H. monstrosus*, the top 6% achieves 79% of the total matings). (f) The most successful ♂♂ are found in a few particular centres within each lek.

Reproduction and Population Structure Litter-size: one. At 00°04'N (Makokou, Gabon), the reproductive chronology is continuous bimodal polyoestry with postpartum oestrus (Bradbury 1977). Each ♀ has two litters/year; gestation 5–6 months. Females in reproductive synchrony. Parturition occurs in the two dry seasons (Dec–Feb and Jun–Jul) so pregnancy and lactation occur mainly in the wet seasons. Data from elsewhere are minimal and inconclusive but consistent with bimodal polyoestry. Sex ratio at birth 1 : 1.

Predators, Parasites and Diseases Ectoparasites include a bat-fly *Dipseliopoda arcuata* (Diptera: Nycteribiidae) and mites *Ancystropus aethiopicus* (Acari: Spinturnicidae), *Mycteronyssus polli* (Acari: Gastronyssidae), *Teinocoptes auricularis* (Acari: Teinocoptidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

GENUS *Lissonycteris*

Angolan Soft-furred Fruit Bat

Lissonycteris K. Andersen, 1912. Cat. Chiroptera Brit. Mus. I. Megachiroptera 23: 814. Type species: *Cynonycteris angolensis* Bocage, 1898.

Lissonycteris is currently considered to be a monotypic genus. It is endemic to Africa. Diagnostic characters: no white basal ear-patches and no white markings on the face; FA: 68–90 mm, adult

♂♂ with ruff of stiff hairs around throat; toes partly webbed (Figure 45), five upper and six lower cheekteeth; M² not greatly reduced (Table 11 p. 228). The palatal ridges and craniodental

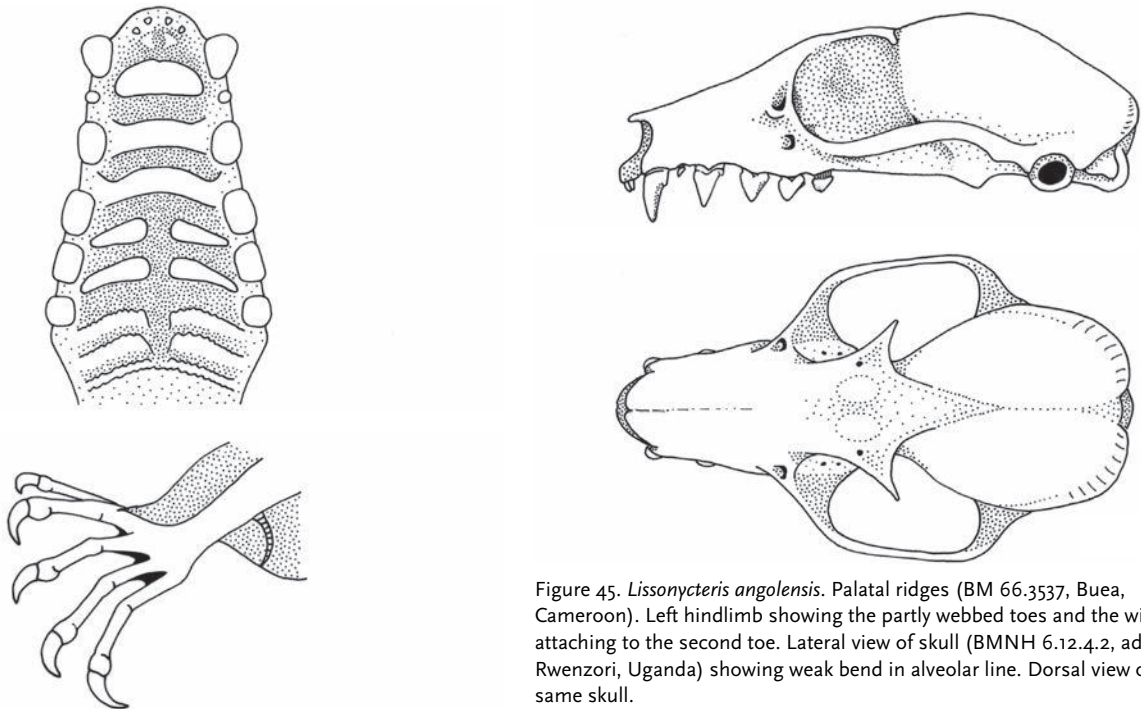

Figure 45. *Lissonycteris angolensis*. Palatal ridges (BM 66.3537, Buea, Cameroon). Left hindlimb showing the partly webbed toes and the wing attaching to the second toe. Lateral view of skull (BMNH 6.12.4.2, adult ♂, Rwenzori, Uganda) showing weak bend in alveolar line. Dorsal view of same skull.

characters of *Lissonycteris* are shown in Figure 45. *Lissonycteris* has longer silkier pelage than other fruit bats. It and the two endemic species of *Rousettus* are the only African fruit bats that normally roost in caves but, unlike *Rousettus* which roost in dark caves and orientate acoustically with a simple form of echolocation (as well as with vision), *Lissonycteris* uses only the eyes and it roosts in caves that are dimly lit. The tiny web between the toes, and the ruff of specialized hairs around the throat in adult ♂♂, are characters that *Lissonycteris* shares with *Myonycteris*.

Lissonycteris was proposed as a subgenus of *Rousettus* by Andersen (1912a) and then raised to generic status by Schwartz (1920). Subsequently, *Lissonycteris* has been considered synonymous with *Rousettus* by Koopman (1975), as a subgenus of *Rousettus* by Hayman & Hill (1971) and Koopman (1993), and as a synonym (or perhaps subgenus) of *Myonycteris* by Peterson *et al.* (1995). In contrast, the generic status of *Lissonycteris* has been maintained by Novick (1958a), Lawrence & Novick (1963), Rosevear (1965), Haiduk *et al.* (1981), Kirsch *et al.* (1995) and many others (see Bergmans 1997) and by Simmons (2005). Based on his own observations, and those of several other authors (including Benedict 1957, Lawrence & Novick 1963 and Kingdon 1974), Bergmans (1997) reported that *Lissonycteris* differs

from *Rousettus* in its skull morphology, dentition, its webbed toes, ruff, the scales of its hairs, its karyotype and chromosomal evolution, its lack of acoustic orientation and its feeding, roosting, locomotion and social behaviour. Bergmans (1997) considers that *Lissonycteris* and *Myonycteris* are more closely related to each other than each is to *Rousettus*. Kirsch *et al.* (1995), on the basis of DNA hybridization, also concluded that *Lissonycteris* is not part of *Rousettus*. Juste *et al.* (1997), on the basis of molecular data, concluded that *Lissonycteris angolensis*, *Myonycteris torquata* and *M. brachycephala* were a monophyletic group, and that the maintenance of *Lissonycteris* within the genus *Rousettus* was not sustainable. Consequently, *Lissonycteris*, which (as subspecies of *Rousettus*) was placed in the *Rousettus* section of Andersen (1912a), was placed in the subfamily Epomophorinae (tribe Myonycterini) by Bergmans (1997). Subsequently, other phylogenetic studies have supported the close relationship between *Lissonycteris* and *Myonycteris* (e.g. Álvarez *et al.* 1999, Giannini & Simmons 2003, 2005).

Following Bergmans (1997) and Simmons (2005), *Lissonycteris* is provisionally considered here to contain only one species, *L. angolensis*.

Meredith Happold

Lissonycteris angolensis ANGOLAN SOFT-FURRED FRUIT BAT

Fr. Lissonyctère d'Angola; Ger. Angolanischer Samtfell-Flughund

Lissonycteris angolensis (Bocage, 1898). J. Sci. Math. Phys. Nat. Lisboa, ser. 2, 5: 133. Pungo Andongo, Cahata, Quibula, Angola.

Taxonomy Originally *Cynonycteris angolensis*. Synonyms: *crypticola*, *goliath*, *petraea*, *ruwenzorii*, *smithii*. Subspecies: five. Peterson *et al.* (1995) and Cotterill (2001a) consider *smithii* to be a distinct species, but Kock *et al.* (2002) agrees with Bergmans (1997) that *smithii* is a subspecies of *L. angolensis*. Based mainly on the apparent geographic isolation of the populations of *goliath* and *petraea* (and differences in size), *goliath* and *petraea* are considered to be distinct species by Cotterill (2001a). However, it is not certain that these populations are really isolated, and the differences in size possibly reflect clinal variation. Therefore, pending further studies, *smithii*, *goliath* and *petraea* are tentatively treated here as subspecies of *L. angolensis* (following Bergmans 1997), but the possibility that *L. angolensis* might contain more than one species is recognized. Since this profile was submitted, specimens were collected from Malawi that appeared to be intermediate in size between *goliath* and *ruwenzorii*, thereby supporting clinal variation (Šklíba *et al.* 2007). Chromosome number (Cameroon): $2n = 36$; $aFN = 66$ (Haiduk *et al.* 1981).

Description Small fruit bat with long silky dark brown pelage; head without white or pale markings; no epaulettes; toes partially webbed (sometimes inconspicuous); ruff of coarse hairs around the throat of ♂♂. Sexes similar in colour and size. Pelage soft, dense and without sheen; extending dorsally and ventrally along each upper arm and for some distance along each forearm, and also extending dorsally onto the interfemoral membrane and hindlegs as far as the ankles; mid-dorsal underfur ca. 10 mm long interspersed with longer hairs. Dorsal pelage ranging from rich dark rusty-brown to dark golden-brown or greyish-brown (becoming darker

on head and rusty-brown on hindlegs and wing margins in some individuals); hairs with basal half pale brown, terminal half dark brown. Ventral pelage slightly paler and greyer. Adult ♂♂ with a ruff of stiff coarse hairs on throat and sides of neck that ends with a whorl on each shoulder. Ruff sometimes sticky. Females lack a ruff of coarse hairs, but the hairs in this region are sparser and longer than elsewhere. No markings on head. Muzzle comparatively short giving the head a puppy-like appearance; lips and cheeks expansible. Ears rounded at tip, naked, dark brown. Antitragus distinct (cf. *Rousettus lanosus*). Palate normally with three undivided thick ridges, and four divided thick ridges of which two are postdental (Figure 45). Wing-membranes dark brown; attaching to second toe. Hindfeet with webbing between the proximal quarter or third of the first phalanges of the toes (Figure 45). Tail very short (8–21 mm).

Skull (Figure 45) on average short for an African fruit bat. Rostrum of medium relative length. Premaxillae fused, including anteriorly (cf. *Eidolon*, *Rousettus* and usually *Myonycteris*). Braincase only slightly deflected; upper alveolar line with weak angle between the two large premolars (Figure 46a) (cf. *Rousettus*, Figure 46c). Upper cheekteeth, particularly the posterior upper premolar (P^4) and anterior upper molar (M^1), are squarish in occlusal view (Figure 46d) (cf. *Myonycteris* Figure 46e). Dental formula $2^{132}/_{2133} = 34$.

Geographic Variation Five subspecies are recognized by Bergmans (1997):

L. a. angolensis: west of 22° E from Angola to E Nigeria (but not yet recorded in Gabon). FA: 72.0–83.0 mm ($n = 44$); GLS: 38.7–41.7 mm ($n = 20$).

L. a. smithii: West Africa, west of 2° E. Less extensively webbed toes. Relatively small and little-differentiated teeth. FA: 67.8–77.7 mm (n = 74); GLS: 36.6–40.1 mm (n = 52) (Bergmans 1997).

L. a. ruwenzorii: east of 22° E and between 6° N and 12° S. Slightly smaller than nominate subspecies (FA: 72.3–84.4 mm [n = 177]; GLS: 39.1–43.8 mm [n = 115]).

L. a. petraea: east of 34° E and north of 6° N; Ethiopian Highlands. FA: 71.7–76.3 mm (n = 10); GLS: 38.5–41.3 mm (n = 6); canines and cheekteeth short and low.

L. a. goliath: east of 30° E and south of 16° S; Mozambique and Zimbabwe. FA: 81.9–89.6 mm (n = 7); GLS: 42.2–46.0 mm (n = 7).

Similar Species Four other African mainland species of fruit bats are small to medium-sized (FA: 56–107 mm) with no basal ear-patches and no other white or pale markings on the head:

Rousettus aegyptiacus. Usually larger (FA: 82–106 mm). Dorsal pelage shorter; no ruff in adult ♂♂; toes not webbed; wing-membranes attaching to first toe or between first and second toes. Upper alveolar line straight. Orientates acoustically as well as visually.

R. lanosus. Usually larger (FA: 85–95 mm). No ruff in adult ♂♂; antitragus indistinct; toes not webbed; wing-membranes attaching to second toe or between first and second toes. Upper alveolar line straight; cheekteeth narrow. Probably orientates acoustically as well as visually.

Myonycteris torquata. Smaller (FA: 56–67 mm). Distal quarter to third of tibia practically naked. Skull with premaxillae not fused; posterior upper premolar (P⁴) and first upper molar (M¹) oblong (occlusal view). Not known to roost in caves.

M. relicta. Interfemoral membrane with pelage only close to the legs. Skull with premaxillae not fused; posterior upper premolar and first upper molar oblong (occlusal view); five lower cheekteeth on each side. Not known to roost in caves.

Distribution Endemic to Africa. Appears to have a very disjunct distribution in the Rainforest BZ and adjacent Rainforest–Savanna Mosaics, the Afroalpine–Afroalpine BZ of Ethiopia, and the Guinea Savanna and Zambezian Woodland BZs. Recorded from Senegal to Ethiopian Highlands (mostly south of 11° N), and southwards to 20° S. Also Bioko I. Some of the gaps, but not all, separate the five subspecies (see Geographical Variation). Map based on Bergmans (1997). Subsequently recorded from Zomba Plateau, Malawi (Šklíba *et al.* 2007); not mapped.

Habitat Rainforest, montane forest, forest transitions and mosaics and, to a lesser extent, woodland savannas, from sea level to 2200 m, where fruiting trees (and usually caves) are present. Most localities in rainforest are near the edges, and much of the rainforest is apparently not inhabited. In the Guinea Savanna and Zambezian Woodland BZs, usually found in relict and riverine forests or in nearby wetter types of woodland.

Abundance Unknown. Apparently common in some localized areas where fruiting trees and caves or cave-like day-roosts are present, but the distribution is likely to be very patchy because of the patchy distribution of this combination of resources.

Adaptations Aspect ratio low; wing-loading not known. Flight predicted to be slow and highly manoeuvrable; this species can probably fly through thicker vegetation than can many other African fruit bats. Unlike all African fruit bats except *Rousettus* spp., most often reported roosting by day in caves and mine-adits, but has also been found in a hollow tree, an open tunnel-like space between huge rocks, a subterranean bunker and a hut (Bergmans 1997). Roosting in foliage seems abnormal but there is a record of two under dead palm-leaves (Bergmans 1979). Because it orientates visually, without

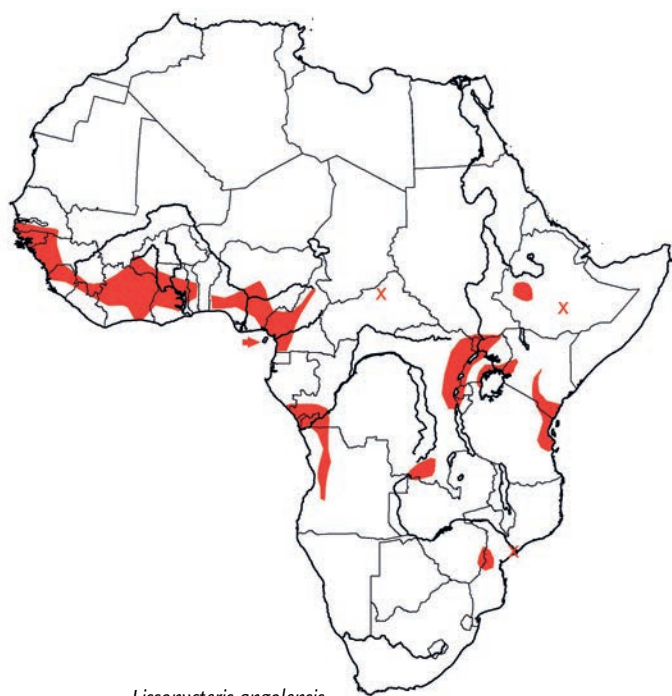

Figure 46. Some diagnostic characters of *Lissonycteris*, *Myonycteris* and *Rousettus*. Lateral views of upper alveolar lines in (a) *Lissonycteris angolensis*, (b) *Myonycteris torquata* and (c) *Rousettus aegyptiacus*. Occlusal views of upper teeth in (d) *Lissonycteris angolensis* and (e) *Myonycteris torquata*.

*Lissonycteris angolensis*

echolocation, it roosts where it is never totally dark. Hangs freely from ceilings of caves, using footholds that can be reached from flight. Does not use its wings for any form of locomotion except flight and, unlike species of *Rousettus*, does not clamber around or crawl into crevices (Lawrence & Novick 1963). Known to share caves with *Rousettus aegyptiacus* and microbats including *Rhinolophus macclaudi*, *Hipposideros caffer* and *H. cyclops*.

Foraging and Food Frugivorous. Forages below the canopy (Juste & Perez del Val 1995). Lands directly on fruits and does not clamber over branches (Lawrence & Novick 1963). Fruit is chewed *in situ*, or carried in the expansible cheeks to a nearby perch where it is chewed, the juice swallowed and the rest discarded. Food in the mouth is manipulated with a hindfoot but not with the wrists or thumbs. Feeds on soft fruits of endemic and introduced trees including *Ficus*, *Anthocleista*, *Chlorophora*, *Solanum* and *Adenia* (Marshall 1985) and orchard fruits including mangoes and guavas. Apparently there are no records of this species visiting flowers. Carnivory has been observed in captivity: on several occasions a captive individual settled over an adult *Myonycteris torquata*, enclosed it with the wings and then ate it, discarding only the feet and fragments of the wings (Coe 1975). In captivity, the mean \pm 1 S.D. nightly consumption of food was 68.9 ± 6.5 g ($n = 17$); the mean consumption per unit body weight was $1.18 \text{ g/g}^{\text{bwt}}$ ($n = 7$); the mean through-put time was 50 ± 14 min, and the percentage dry weight assimilated was 86% (Wolton *et al.* 1982).

Social and Reproductive Behaviour Usually roosts in groups of 2–50 (rarely up to 100); occasionally roosts singly. Females near parturition or lactating roost in maternity-roosts in which adult δ δ are absent or rare (Eisentraut 1942, 1956, 1963, Happold & Happold 1978). Evidence from Liberia suggests that the adult δ δ move away from some areas leaving the females behind until parturition and lactation are over (Wolton *et al.* 1982). Kingdon (1974) reports that the ‘stickiness’ of the males’ ruffs appears to increase and decrease

from time to time and he suggested that this may be caused by glandular secretion associated with sexual behaviour, and Hickey & Fenton (1987) found that the form of ‘glandular hairs’ from the ruff was consistent with a scent-dispersing function. However, Mainoya & Howell (1979) found almost no glandular tissue in the neck skin, and suggest that the ruff provides visual rather than olfactory cues.

Reproduction and Population Structure Litter-size: one. Reproductive chronology uncertain – probably polyoestry at least in some localities. At ca. $07^{\circ}40'N$ (Mt Nimba, Liberia), 71% of 49 females were pregnant in Jul and gave birth in Sep (Wolton *et al.* 1982), and near-parturient females were also recorded in late Nov (Coe 1975). At $07^{\circ}35'N$ (Ipole, Nigeria), a maternity group in Jul included six palpably pregnant females , one lactating female , five parous and seven non-parous females of undetermined reproductive condition, and two adult-sized males with abdominal testes (Happold & Happold 1978). On Bioko I., 29 of 32 females were pregnant and three reproductively inactive in Feb, 5 of 5 pregnant in Mar, 9 of 16 pregnant and seven (including three subadults) reproductively inactive in Oct, 2 of 3 pregnant and one lactating in Nov, and 2 of 4 lactating and two reproductively inactive in Dec (no useful data for other months) (Eisentraut 1964); this suggests polyoestry. In S Congo, near-parturient females have been recorded from May to Sep and in Nov, and lactation in Jan–Feb and Jun (Adam & Le Pont 1974). Longevity record (in captivity) 22 years 11 months (Jones 1982).

Predators, Parasites and Diseases Ectoparasites include bat-flies *Cyclopodia greeffi*, *Dipseliopoda biannulata*, *D. setosa* (Diptera: Nycteribiidae); mites *Microtrombicula hexasternalis*, *Riedlinia rousetti*, *Chiroptella adami* (Acari: Trombiculidae), *Nycteridocoptes macrophallus* (Acari: Sarcoptidae), *Teinocoptes ituriensis*, *Chirobia squamata* (Acari: Teinocoptidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Assessment includes all subspecies. Subspecies *goliath* and *petraea* are threatened by destruction of habitat and are likely to be taken from caves for bushmeat.

GENUS *Megaloglossus*

Woermann's Long-tongued Fruit Bat

Megaloglossus Pagenstecher, 1885. Zool. Anz. 8: 245. Type species: *Megaloglossus woermanni* Pagenstecher, 1885.

Megaloglossus is a monotypic genus, endemic to Africa. Diagnostic characters: no white basal ear-patches; no white markings on face; FA: 38–49 mm; tongue very long with conspicuous long papillae on the pointed tip (Figure 35c); adult ♂ with a white, yellow or orange ruff; five upper and six lower cheekteeth (Table 11, p. 228). Selected characters of *Megaloglossus woermanni* are illustrated in Figure 47.

Megaloglossus has been placed in the Eonycterine section of Andersen (1912a) and in the subfamily Macroglossinae with all other specialized nectar-feeding pteropodids (e.g. Koopman 1993). However, DNA hybridization (Kirsch *et al.* 1995) and characters of the female reproductive system (Hood 1989) indicate that *Megaloglossus* and the other genera in this subfamily do not have a monophyletic origin, and

that *Megaloglossus* acquired nectarivory independently of the other genera. Based on these and other studies, Bergmans (1997) placed *Megaloglossus* in the subfamily Epomophorinae (tribe Myonycterini). The close relationship between *Megaloglossus*, *Myonycteris* and *Lissonycteris* is supported by the recent molecular studies of Álvarez *et al.* (1999) and Giannini & Simmons (2003). Several morphological characters of the integument and the postcranial skeleton also support Myonycterinae containing *Megaloglossus*, *Myonycteris* and *Lissonycteris* (Giannini & Simmons, 2005).

The single species is *Megaloglossus woermanni*.

D. C. D. Happold & Meredith Happold

Megaloglossus woermanni WOERMANN'S LONG-TONGUED FRUIT BAT

Fr. Mégaloglosse de Woermann; Ger. Woermanns Langzungen-Flughund (Afrikanishchen Langzungen-Flughund)

Megaloglossus woermanni Pagenstecher, 1885. Zool. Anz. 8: 245. Sibange Farm, Gabon [probably near Libreville, Gabon].

Taxonomy Synonyms: *prigoginei*. Subspecies: none currently recognized, but see Geographic Variation. Chromosome number (Cameroon, Gabon): $2n = 34$; $aFN = 62$ (Haiduk *et al.* 1980, Primus *et al.* 2006).

Description Very small, dainty, dark brown fruit bat with long, pointed muzzle and long, brush-tipped tongue; no markings on head; no epaulettes. Sexes similar in size. Pelage soft, moderately dense; mid-dorsal hairs 6–8 mm. Dorsal pelage dark brown; hairs pale brown with dark brown at tip. Ventral pelage paler. Adult ♂ with

ruff of stiff white, yellow or orange hairs on throat, neck and upper part of chest; hairs sometimes slightly sticky. Head small and narrow, with long, pointed muzzle; uniformly dark brown. Ears rounded at tip, blackish-brown. Eyes large. Tongue long and narrow; tip pointed and covered with brush of hair-like papillae (Figure 35b). Palate with seven ridges; ridges 5 and 6 divided by median groove (Figure 47). Wings dark brown; wing-membranes attaching to second or third toes, or between these toes; fifth finger shorter than third. Toes occasionally very weakly webbed (Figure 47). Tail very short (two vertebrae).

Skull (Figure 47) short for an African fruit bat. Braincase very rounded, sloping fairly steeply downwards from near front to back. Rostrum relatively long, narrow and tapering. Teeth weak (except canines); cheekteeth very low, narrow and devoid of cusps. Dental formula $^{2132}_{2133} = 34$.

Geographic Variation Two subspecies have been described:

M. w. woermanni: Throughout most of geographic range.

M. w. prigoginei: E DR Congo. FA: 43–49 mm; GLS: 27.7–30.3 mm.

However, the subspecific distinction between the supposedly larger *prigoginei* and smaller *woermanni* is not substantiated because there is considerable variation in size in all populations, as well as a gradual clinal increase in FA and GLS from west to east (Bergmans & Van Bree 1972, Bergmans 1997). There is also a large specimen from Angola (Bergmans 1997).

Similar Species None. This is the only African fruit bat with a long, narrow, pointed, brush-tipped tongue, no basal ear-patches and no other markings on the head.

Distribution Endemic to Africa. Widespread throughout the Rainforest BZ from Guinea and Sierra Leone to E DR Congo, Gabon and Bioko I., with some records from the Afromontane–Afroalpine BZ. Isolated populations have been recorded close to the Rainforest BZ in the adjacent Rainforest–Savanna Mosaics in West Africa, Uganda, N Angola and S DR Congo. Map based on Bergmans (1997).

Habitat Primary and secondary lowland rainforest, and clearings, banana plantations and other cultivated patches in rainforest. On Bioko I., occurs in rainforest at sea level, montane forest (800–1400 m) and in mossy forest (1400–1800 m) (Juste & Perez del Val 1995). Many specimens have been caught within a few metres of the ground, but the feeding habits of *M. woermanni* suggest that it probably also exploits the higher strata of the rainforest. However, when mist-nets were set in rainforest in Taï N. P., Côte d'Ivoire, at five elevations ('understorey' [1.5 m], 'canopy' [16.5, 20.5, 24.5 and 36.5 m above ground]), six *M. woermanni* were netted in the understorey and only one in the canopy (height 24.5 m; P. Barrière pers. comm.) (Henry *et al.* 2004).

Abundance Until recently, thought to be rare because there were few specimens in collections. However, in selected localities (where food resources are abundant) they may be common. For example: 'very common at Bélinga' in Gabon (Brosset 1966) and 'numerous in clearings in disturbed forest' in Congo (Dowsett *et al.* 1991).

Megaloglossus woermanni

Adaptations By day, hangs freely from half-dried banana and plantain leaves and amongst foliage of shrubs (Rosevear 1965). Also, one was taken inside a hut and another inside a house that had ripe bananas just outside the door (Rosevear 1965). The tongue is modified for lapping nectar from flowers: it is long (20 mm), thin (maximum breadth 5 mm) and tapers towards the tip, which is densely covered by rows of backward-pointing hair-like papillae. The papillae form a felt-like brush in which the nectar is entrapped. During lapping, the tongue is extruded with the tip curled downwards; then the tip is brought forward, and sometimes curled upwards, to scoop nectar into the spaces between the papillae (Kulzer 1982). The tongue moves in and out ca. seven times/second. As in other nectarivorous pteropodids, the cheekteeth are very small and non-functional, sometimes barely breaking through the gums. Because nectar is very easily digested and absorbed, the alimentary canal is short (twice HB) compared with ca. 6.5 HB in fruit-eating pteropodids (Kingdon 1974). Because of its small size, and the limitations imposed by nectarivory, *M. woermanni* does not maintain a constant body temperature (Kulzer & Storf 1980). When the ambient temperature is 31 °C, the body temperature is ca. 34 °C. When the ambient temperature falls to 23 °C (as it often does during cooler days and nights in the rainforest), the body temperature falls to ca. 26 °C, the metabolic rate is reduced to ca. one-half that at 31 °C, and the bat becomes torpid. Torpor is a means of saving energy when foraging would be energetically too expensive. Has been mist-netted over water (Jones 1971), suggesting that it might need to drink water – perhaps after roosting and prior to feeding.

Foraging and Food Feeds mainly on nectar and, to a lesser extent, pollen (Brosset 1966). Individuals in captivity refused to eat fruits and insects but avidly drank honey-water (Brosset 1966). Unlike nectarivorous phyllostomid bats of the Americas, which hover like humming-birds while feeding, *M. woermanni* apparently lands on or adjacent to flowers before feeding (Hill & Smith 1984). It feeds

by inserting the long tongue into the corolla of flowers and lapping the nectar (see Adaptations). In Nigeria (Happold & Happold 1978) and Bioko I. (Juste & Perez del Val 1995), they have been found in the lower strata (subcanopy) of the rainforest with frugivorous *Scotonycteris zenkeri* and, on Bioko I., also with *Rousettus aegyptiacus* and *Lissonycteris angolensis*. It is likely, however, that *M. woermanni* also forages in the higher strata: further investigations with elevated mist-nets are needed to confirm this prediction. Plants known to be exploited for food include *Kigelia* flowers (Eisentraut 1963) and pawpaw flowers for nectar (Jeffrey 1975), but it is highly likely that nectar is also taken from a wide variety of rainforest plants. Although flowers are present throughout the year in the rainforest, *M. woermanni* is not always present at particular localities, suggesting that it might be nomadic. For new information about home-range and foraging behaviour, see Weber *et al.* (2009).

Social and Reproductive Behaviour Very little is known. The only records of roosting are for male bats that were found singly (Brosset 1966). In Gabon (Brosset 1966) and Ghana (Jeffrey 1975), ♂♂ alone have been captured in large numbers ($n = 86$, Belinga, Gabon over several years; $n = 11$ on one night in Ghana), but at other times and localities both sexes have been obtained, although ♂♂ have predominated (e.g. 79% ♂♂ [$n = 109$] at Mt Nimba, Liberia; Wolton *et al.* 1982). Many ♂♂ have been mist-netted together at the same time, suggesting that they were part of a 'feeding flock', or that there was a 'male roosting area' nearby (Wolton *et al.* 1982). These observations suggest a social organization in which ♂♂ and ♀♀ segregate at least during some parts of the year (Happold 1987), but this needs confirmation.

Reproduction and Population Structure Litter-size: one, occasionally two (Eisentraut 1973b, Czekala & Benirschke 1974). Reproductive chronology uncertain. In equatorial Uganda, Okia (1987) recorded simultaneous pregnancy and lactation in one ♀ in May, and one birth in Jan. He recorded 1 of 3 ♀♀ pregnant in Jan,

1 of 3 pregnant in Feb, 1 of 1 pregnant in Apr and in May and 4 of 4 near parturition in Sep. These data are consistent with bimodal polyoestry with births in Jan and Sep (as in three other species of fruit bats in Uganda), but this needs confirmation: aseasonal polyoestry is an alternative possibility. Data from elsewhere are fragmentary and inconclusive (e.g. Eisentraut 1964, Jones 1971, Bergmans 1979, Wolton *et al.* 1982). Gestation not known.

Predators, Parasites and Diseases Ectoparasites include a mite *Binuncus megaloglossus* (Acari: Myobiidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Major threats: reduction in area of rainforest, and changes in the structure and biodiversity of the rainforest.

GENUS *Micropteropus* Lesser Epauletted Fruit Bats

Micropteropus Matschie, 1899. Megachiroptera Berlin Mus., p. 36, 57. Type species: *Epomophorus pusillus* Peters, 1868.

Micropteropus is a polytypic genus with two species, *M. pusillus* and *M. intermedius*, which are endemic to Africa. Diagnostic characters: white basal ear-patches but no other white markings on the head; FA: 46–64 mm, epaulettes on shoulders of adult ♂♂; muzzle simple; interfemoral membrane well developed and with calcars; 5–6 thick palatal ridges of which all but the first are divided by a wide median groove; C–M¹: 8.0–ca. 10.6 mm; usually three upper and five lower cheekteeth (very occasionally four upper cheekteeth) (Table 11, p. 228). Selected characters of *Micropteropus* are illustrated in Figure 48.

Micropteropus was placed in the *Epomophorus* section of Andersen (1912a), and is in the subfamily Epomophorinae (tribe Epomophorini) of Bergmans (1997). *Micropteropus* is evidently very closely related to *Epomophorus*: the type species was originally assigned to *Epomophorus* and *Micropteropus* was originally proposed as a subgenus of *Epomophorus*. It was raised to generic status by Andersen (1910) mainly because

of the relatively short muzzle and aberrant soft palate of the type, *M. pusillus* (the other criteria are listed and discussed by Bergmans 1989). More recent phylogenetic studies, based on molecular characters, support the close relationship between *Micropteropus* and *Epomophorus* (e.g. Álvarez *et al.* 1999, Giannini & Simmons 2003). Many morphological characters also support a close phylogenetic relationship of *Micropteropus* and *Epomophorus* (Giannini & Simmons 2005). Whereas most species of *Epomophorus* have six thick palatal ridges of which ridges 2, 3 and 4 are undivided, *M. pusillus* and *M. intermedius* have essentially six of which all but the first are close together and divided by a wide median groove. In *M. pusillus* and *M. intermedius*, partial fusions between ridges 2 and 3, and/or 3 and 4, may result in the number of ridges appearing to be less than six. A third species, *M. grandis*, which is morphologically intermediate between *M. intermedius* and *Epomophorus* (especially *E. labiatus*), was transferred to

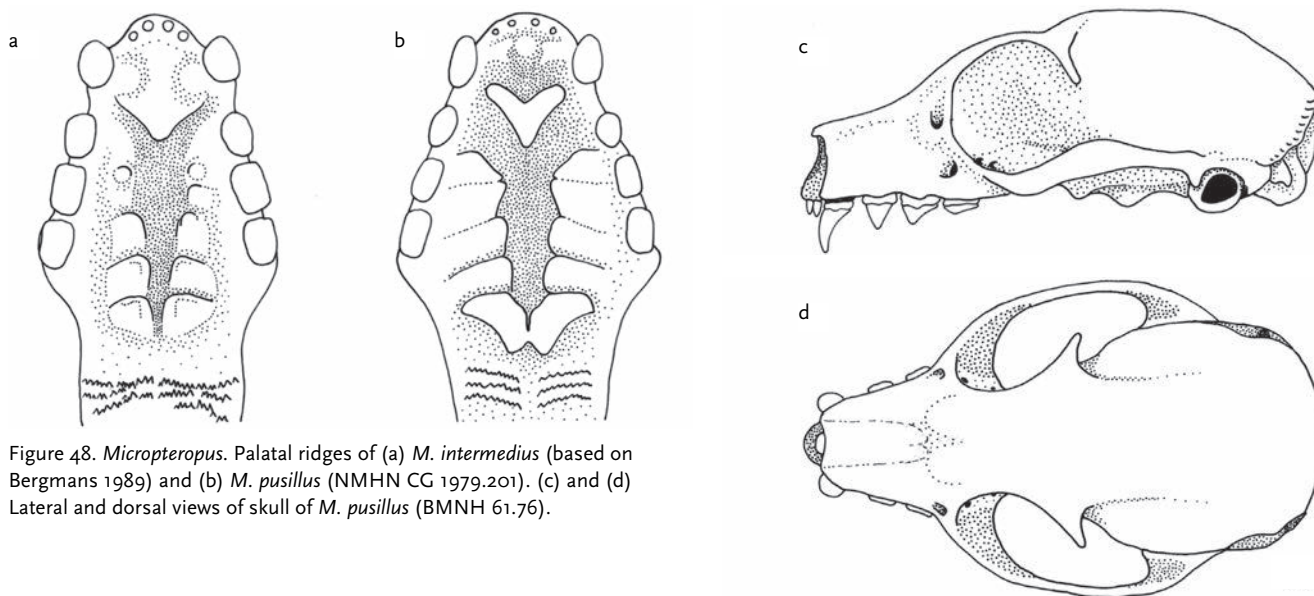

Figure 48. *Micropteropus*. Palatal ridges of (a) *M. intermedius* (based on Bergmans 1989) and (b) *M. pusillus* (NMHN CG 1979.201). (c) and (d) Lateral and dorsal views of skull of *M. pusillus* (BMNH 61.76).

Epomophorus by Bergmans (1988). Chromosomal differences between *Epomops*, *Hypsignathus*, *Micropteropus* and *Epomophorus* offer an additional argument for maintaining the generic status of *Micropteropus* (Haiduk *et al.* 1980, 1981). Further investigations may resolve the affinities of *E. grandis* and perhaps indicate when and where the two genera became separated.

The two species can be distinguished by the following characters:

M. intermedius. Larger, FA: 57–64 mm, GLS: 32–34 mm. Palatal ridges 2 and 3 weakly developed and apparently fused in some specimens. *M. pusillus*. Smaller, FA: 46–56 mm, GLS 26–31 mm. All palatal ridges prominent and well defined; 2 and 3 may be fused, 4 and 5 fused occasionally.

Meredith Happold

Micropteropus intermedius HAYMAN'S LESSER EPAULETTED FRUIT BAT

Fr. Microptéropode de Hayman; Ger. Haymans Kleiner Epaulettenflughund

Micropteropus intermedius Hayman, 1963. Publç. Cult. Comp. Diamantes de Angola, 66: 100. Dundo, Lunda, Angola.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Very small to small, fawn fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; six thick palatal ridges of which the posterior five are divided, all except numbers 2 and 3 are well developed and two are clearly postdental; FA: 57–64 mm. A poorly known species – only one adult ♂ and four adult ♀♀ known. Sexes apparently similar. Pelage soft, moderately long. Dorsal pelage pale brown (fawn) becoming paler on shoulders; hairs with medium sepia brown at base. Ventral pelage pale brown becoming darker on flanks. Adult ♂♂ have a conspicuous white epaulette on each shoulder, which retracts into a pouch rimmed by sepia brown pelage: adult ♀♀ have a whorl of hairs, same colour and length as dorsal hairs, on each shoulder. Head round and puppy-like, pale brown with medium sepia brown chin and throat; white basal ear-patches. Muzzle relatively short and blunt; lips and cheeks not very expansible. Six palatal ridges, 5 and 6 divided by medial gap (Figure 48a); ridges 2 and 3 weakly developed and apparently fused in some specimens (cf. *M. pusillus*). Ears rounded, naked, with brown pigmentation. Eyes very large. Wing-membranes brown; attaching to second toe. Interfemoral membrane narrow; calcaris present. Tail rudimentary.

Skull short for an African fruit bat. Rostrum of medium relative length (34–35% of GLS [$n = 3$]), but broad (Bergmans 1989). Postdental palate almost flat. Dental formula usually $^{2121}_{2132} = 28$ very occasionally an extra upper premolar (P^1) is present.

Geographic Variation None.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Micropteropus pusillus. Smaller (FA: 46–56 mm; GLS: 26.8–31.0 mm).

All palatal ridges prominent and well defined.

Epomophorus grandis. Larger in most skull and tooth dimensions including, in particular, rostrum length (13.1–13.7 mm), palatal length (20.2–20.9 mm) and C–M¹ (11.8–12.3 mm). In adults, palatal ridges 2–6 are divided.

Epomophorus (all other species). Palatal ridges 2–4 not divided by medial gap.

Epomops (3 spp.). Three or five thick palatal ridges.

Nanonycteris veldkampii. Smaller (FA: 46–54 mm, GLS: 23.6–27.1 mm).

Distribution Endemic to Africa. Known from only four localities in the Southern Rainforest–Savanna Mosaic, in NE Angola and SW DR Congo (Hayman 1963, Bergmans 1989). Bergmans suggests that this species is likely to occur in woodland savannas of the Zambezian Woodland BZ, but is not likely to occur in the Rainforest BZ.

Habitat Mosaics of forests (including lowland rainforest, mangrove forest and coastal forest) with open vegetation such as secondary grasslands (Bergmans 1989).

Abundance Very rarely collected.

Remarks A pregnant ♀ with one foetus (FA: ca. 14 mm) was taken in Jun–Jul (Bergmans 1989). Nothing else is known about the biology of this species.

Conservation IUCN Category: Data Deficient.

There is no evidence that this species is rare in the field, and its habitat preferences, distributional limits and population dynamics have not been investigated (Bergmans 1999).

Micropteropus pusillus PETERS'S LESSER EPAULETTED FRUIT BAT

Fr. Petit microptéropode; Ger. Peters' Kleiner Epaulettenflughund

Micropteropus pusillus (Peters, 1868). Monatsber. K. Preuss. Akad. Wiss. Berlin 1867: 870 (publ. 1868). Yoruba, Nigeria.

Taxonomy Originally *Epomophorus pusillus*. Synonyms: none. Chromosome number (Cameroon): 2n = 35; aFN = 64 (Haiduk *et al.* 1981).

Description Very small fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂ ♂; six thick palatal ridges of which the posterior five are divided and well developed (including 2 and 3), and two are clearly postdental; FA: 46–56 mm. Sexual dimorphism not pronounced; ♀ ♀ with, on average, larger forearms. Pelage soft, dense dorsally, sparser ventrally especially on throat; extending onto forearm, propatagium and interfemoral membrane; mid-dorsal hairs 7–9 mm. Dorsal pelage medium brown, reddish-brown, greyish-brown to pale brown; hairs with pale base. Ventral

pelage paler, sometimes off-white but without a demarcated whitish mid-ventral patch. Adult ♂ ♂ have a white epaulette on each shoulder (retracted into a pouch rimmed by dark hairs except when displayed); adult ♀ ♀ have a whorl of hairs, same colour and length as dorsal hairs on each shoulder. Ears brown. Eyes large. Head rounded and puppy-like with white or pale yellow basal ear-patches but no other markings; muzzle short and broad; lips and cheeks moderately expansible. Palate with six thick ridges, the first hastate (pointing backwards), all others divided by a medial gap decreasing in width from front to back and ending with V-shaped notch in ridge 6, ridges 2 and 3 not weakly developed (cf. *M. intermedius*), ridge 4 partly postdental, ridges 5 and 6 postdental (cf. *E. grandis*) (Figure 48b). Wing-membranes chocolate brown; attaching to second toe. Tail rudimentary or absent.

Skull (Figure 48) short for an African fruit bat. Rostrum, on average, relatively short (31–36% of GLS) and broad (Bergmans 1989). Postdental palate almost flat. Dental formula: $^{2121}_{2132} = 28$.

Geographic Variation Specimens are quite uniform throughout geographic range, with no clear clinal variation being apparent (Bergmans 1989). One exception is that specimens from Côte d'Ivoire have slightly longer forearms than specimens from elsewhere and weigh ca. 20% more than specimens from Equatorial Guinea.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂ with epaulettes; three upper and five lower cheekteeth:

Micropteropus intermedius. Larger (FA: 57–64 mm; GLS: 32.0–33.3 mm, $n = 3$). Palatal ridges 2 and 3 weakly developed.

Epomophorus grandis. Larger (FA: 62–66 mm; GLS: 35.4–36.7 mm, $n = 3$).

Epomophorus (all other spp.). Palatal ridges 2–4 not divided by medial gap.

Epomops (3 spp.). Three or five thick palatal ridges.

Nanonycteris veldkampii. Nine thick or partly thick palatal ridges, all interdental ridges undivided.

Distribution Endemic to Africa. Recorded mainly from the Guinea Savanna BZ and Rainforest–Savanna Mosaics, with extensions into the Sudan Savanna, Rainforest, Somalia–Masai Bushland and Zambezan Woodland BZs. Recorded from Senegal to Ethiopia and southwards to Angola, S DR Congo and NW Tanzania – but avoiding the Congolian rainforest except around its edges.

Habitat Essentially a low elevation, savanna-forest ecotone species found along edges of gallery forests and in secondary growth in moist Guinea Savanna habitats, and in woodland copses in Sudan Savanna. Probably penetrates into rainforests along roadways, cut-overs, plantations and agricultural clearings. Generally uncommon in closed rainforest habitats. Mostly recorded below 800 m.

Abundance Uncommon in closed-canopy forest, but locally very common in regeneration and secondary growth and along forest edge, particularly where free-standing fig trees are abundant. A year-round resident with numerous recaptures of marked individuals.

Adaptations Aspect ratio high; wing-loading medium; flight rapid, manoeuvrable, agile and erratic (resembling that of some microbats) (Jones 1972, Norberg & Rayner 1987). Flies beneath, between and through clumps of fairly dense vegetation; begins flights with direct take-off from branches (Jones 1972), and is able to hover well (Kingdon 1974). Thumbs are relatively short and weak. Clumsy when crawling along branches, so accesses fruits only by flight. Roosts by day, hanging freely from branches of low shrubs and trees. Sometimes roosts, well hidden, between leaves of dense bushes, and seldom flies away when disturbed (Lang & Chapin 1917b). Sometimes roosts in places with little cover and considerable exposure to the sun (Verschuren 1957). There is one record of an individual roosting in a palm tree (Rosevear 1965). Some captive individuals exhibited a strong homeothermic response when subjected to temperatures down to 5 °C, but others

Micropteropus pusillus

permit hypothermia, allowing body temperature to decline as low as 22 °C (Jones 1972).

Foraging and Food Primarily frugivorous. Begins foraging at dusk. Typically flies into a fruiting tree, grasps fruit in mouth, and flies off to a feeding-roost 10–50 m distant. Can carry fruits up to 75% of body mass. When feeding, holds large fruit between foot, thumb and second finger, fills cheek pouches to bulging with pulp and small seeds. Slowly sucks to extract juices and some seeds before spitting out fibre-seed pellet. Feeding-roosts used for several days, accumulate piles of spat-out fibre-seed pellets. Feeds on flowers seasonally (5 genera, 4 families), but is primarily frugivorous. Moth scales left on fruits may appear intact in faeces, so do not indicate insectivory (Thomas 1984b). Marshall (1985) lists 11 genera (9 families) of figs and fruit in diet. All figs and fruits are sweet, succulent, larger than 20 mm. In Guinea Savanna of Côte d'Ivoire, diet dominated by *Ficus capensis* and *F. vallis-choudae* (49%), *Vitex doniana* (15%), *Cola gigantea* (12%). Ingests up to 250% of body mass and 1002.2–1428.7 kJ/kg^{0.75} nightly in captivity, adjusting intake by protein content of diet (Thomas 1984a).

Social and Reproductive Behaviour Poorly known. Roosts singly, in twos or in small groups of up to a dozen individuals (Lang & Chapin 1917b, Verschuren 1957). Pregnant ♀♀ continue to roost with immature young. Males make a shrill ringing note similar to that of larger epauletted fruit bats (Kingdon 1974). Calling ♂♂ common and widespread in Sudan Savanna, but not commonly heard in some patches of regenerating Guinea Savanna in Côte d'Ivoire, despite high capture-rates in mist-nets. May suggest geographic or habitat-related differences in social structure and mating behaviour.

Reproduction and Population Structure Litter-size: one ($n = \text{ca. } 20$). In Côte d'Ivoire, the reproductive chronology is continuous bimodal polyoestry with postpartum oestrus. At

06° 13' N (Lamto; Guinea savanna in Rainforest–Savanna Mosaic; rain throughout year with peaks in Apr–Jun and Sep, minimal in Dec–Jan), births occur at onset of the long wet season and the major increase in fruit availability (Mar) and ca. six months later, roughly at onset of short wet season and minor increase in fruit availability (Sep). Gestation ca. six months. Lactation (for population as a whole) for ca. 7–8 weeks after the Mar births, and ca. 11 weeks after the Sep births – the longer second period possibly due to less synchrony between ♀♀. Adult testes length constant at 5.6–6.0 mm, with no annual cycle in size. At 09° 50' N (Wango Fitini in northern part of Comoé N. P.; Guinea Savanna BZ; rainfall unimodal), births occur at onset of wet season (Apr) and at end of wet season (late Oct). At both localities, the first birth period seems timed to match increasing availability of fruit, but the second seems set by the six-month gestation. Juveniles appear in flying population in Apr–May and Nov–Dec at body mass 14–18 g and forearm 46–48 mm. Females mature at six months and give birth to their first young at 12 months. Males begin puberty at seven months and become adult by nine months. Reference: Thomas & Marshall (1984).

Predators, Parasites and Diseases Ectoparasites include mites *Ancystropus aethiopicus* (Acari: Spinturnicidae), *Nycteridocoptes pteropodi* (Acari: Sarcoptidae), *Teinocoptes epomophori*, *T. auricularis* (Acari: Teinocoptidae) (Anciaux de Faveaux 1984). Rift Valley Fever virus (Family, Bunyaviridae; genus, *Phlebovirus*) identified in 7% of individuals in Guinea. Lagos bat virus (strain AnCb-672d, identical to that of *Eidolon helvum*) isolated from brain, heart and spleen in Central African Republic.

Conservation IUCN Category: Least Concern.

GENUS *Myonycteris*

Collared Fruit Bats

Myonycteris Matschie, 1899. Megachiroptera Berlin Mus., p. 61, 63. Type species: *Cynonycteris torquata* Dobson, 1878.

Myonycteris torquata male.

Myonycteris has three species: two in Africa and one (*M. brachycephala*) on the oceanic islands of São Tomé and Príncipe in the Gulf of Guinea. Diagnostic characters: no white basal ear-patches; no white markings on the face; FA: 56–75 mm; ruff of stiff hairs on lower neck of adult ♂♂; tongue moderately long, rounded at tip, with inconspicuous rasp-like papillae; toes partly webbed; visual

orientation only; premaxillae seldom fused; five upper and five or six lower cheekteeth; M² greatly reduced (Table 11, p. 228). The partly webbed toes, palatal ridges and skull of *M. torquata* are shown as a representative of the genus in Figure 49. Figure 49 also shows interspecific differences in upper teeth.

The genus was revised by Bergmans (1976). *Myonycteris* was placed in the *Cynopterus* section of Andersen (1912a), but Bergmans (1997) transferred it to the subfamily Epomophorinae (tribe Myonycterini) on the basis of previous cladistic analyses of morphological characters, which indicated that *Myonycteris* should be excluded from the *Cynopterus* section (Springer *et al.* 1995), and on the basis of phylogenetic relationships (Juste *et al.* 1997), which showed that *Myonycteris torquata* and *M. brachycephala* and *Lissonycteris angolensis* form a monophyletic group. Subsequently, cladistic analysis of other skull and/or genetic characters has repeatedly confirmed this conclusion (e.g. Álvarez *et al.* 1999, Giannini & Simmons 2003, 2005). Two subgenera are recognized by Koopman (1994) and Simmons (2005):

M. (Myonycteris). Cheekteeth comparatively weak; outer and inner ridges of posterior lower premolar fused anteriorly; lower canine at least as high as middle lower premolar; no sagittal crest. Contains African mainland species *M. relictus* and *M. torquata*.

Figure 49. *Myonycteris*. (a) Palatal ridges of *M. torquata* (BMNH 84.799; see De Vree 1971 for variations). (b) Left hindlimb of *Myonycteris torquata* showing attachment of wing to second toe. (c) Lateral view of skull of *M. torquata* (BMNH 77.352, adult M). (d) Occlusal view of upper teeth of *M. relicta* (based on Bergmans 1980). (e) Occlusal view of upper teeth of *M. torquata leptodon* (C-M² drawn to same size in both species).

M. (Phygetis). Cheekteeth comparatively strong; outer and inner ridges of posterior lower premolar well separated; lower canine not as high as middle lower premolar; sagittal crest present. Contains *M. brachycephala* from São Tomé and Príncipe.

However, Bergmans (1976, 1997) does not recognize the subgeneric status of *Phygetis* and, furthermore, the cladistic analyses of Álvarez *et al.* (1999) and Giannini & Simmons (2003) indicate that *M. brachycephala* and *M. torquata* are more closely related than either is to *M. relicta*.

The two African mainland species can be distinguished by size and geographic distribution:

M. relicta. FA: 65–75 mm; GLS: 35.5–39.2 mm. African mainland east of 32° E.

M. torquata. FA: 56–67 mm; GLS: 30.2–35.2 mm. African mainland west of 32° E and Bioko I.

Meredith Happold

Myonycteris relicta BERGMANS'S COLLARED FRUIT BAT

Fr. Myonyctère d'Afrique orientale; Ger. Reliktärer Halskrausen-Flughund

Myonycteris relicta Bergmans, 1980. Zool. Meded. Rijksmus. Nat. Hist. Leiden 14: 126. Mukanda River, Lukore area, Shimba Hills, Kwale District, Coastal Province, Kenya.

Taxonomy Placed in subgenus *Myonycteris* by some authors, but see Genus *Myonycteris*. Synonyms: none. Peterson *et al.* (1995) consider *relicta* to be a species of *Rousettus*. Chromosome number: not known.

Description Small, reddish-brown fruit bat with no basal ear-patches; no white markings on head; no epaulettes; no mantle; ♂♂ with ruff of stiff hairs; interfemoral membrane with pelage only near legs; five lower cheekteeth: FA: 65–75 mm. Sexes similar except for ruff. Pelage dense, woolly on head; extending half-way along forearm and marginally onto wing-membrane, along leg (but

not as far as ankle) and on to interfemoral membrane but only adjacent to legs; mid-dorsal hairs 7–8 mm. Dorsal pelage pale to medium reddish-brown; hairs pale pinkish-brown with reddish-brown at tip. No epaulette or white markings on shoulder. Ventral pelage pinkish-brown; hairs with slightly darker bases. Adult ♂♂ with ruff of comparatively coarse, pale orange to pale orange-brown, specialized hairs on chin, throat and upper chest extending to shoulders. Head without markings; muzzle moderately long; lips quite thick and only slightly expansible. Ears dark brown. Eyes large. Palate with six (possibly sometimes seven) thick ridges, 1–3 undivided, 4–6 divided by narrow medial gaps. Wing-membranes

dark brown; attaching to second toe. Toes 'webbed' to middle of first phalanges.

Skull short and delicate for an African fruit bat. Rostrum of medium relative length (ca. 36–37% of GLS). Dentition comparatively strong (cf. *M. torquata*) and simple; two lower incisors on each side; M^2 and M_2 reduced; M_3 absent (cf. *M. torquata*); P^4 and M^1 oblong and subrectangular in occlusal outline, with longitudinal axes pointing (in forward direction) slightly lingually (Figure 49d) (Bergmans 1980, 1997, Schlitter & McLaren 1981). Dental formula $21^{132}/_{2132} = 32$.

Geographic Variation Not yet assessed but, as the distribution is disjunct, geographic variation is a possibility.

Similar Species Four other African mainland species of fruit bats are small to medium-sized (FA: 56–107 mm) with no basal ear-patches and no other white or pale markings on the head:

Myonycteris torquata. Usually larger (FA: 56–67 mm; GLS: 30.2–35.2 mm). Interfemoral membrane entirely covered by pelage. Six lower cheekteeth on each side.

Lissonycteris angolensis. Interfemoral membrane well covered with pelage. Skull with premaxillae fused; P^4 and M^1 squarish (occlusal view: Figure 46d); six lower cheekteeth on each side. Roosts in caves.

Rousettus (2 spp.). Larger (FA: 82–106 mm).

Distribution Endemic to Africa. Recorded disjunctly from the Coastal Forest Mosaic BZ (from SE Kenya to SE Tanzania), and from two isolated localities in the Zambezian Woodland BZ – at the eastern escarpment of the Uzungwa Mts in Tanzania, and at the confluence of the Haroni and Rusitu Rivers (= Lusitu River) in E Zimbabwe (Schlitter & McLaren 1981, Burgess *et al.* 1992, Mickleburgh *et al.* 1992, Burgess & Muir 1994, Clarke 1995, Clarke & Dickinson 1995, Cotterill 1995, Bergmans 1997, Burgess *et al.* 2000a, b, D. Kock unpubl.).

Habitat Forests in the coastal forest mosaic of East Africa, and inland lowland forests, at altitudes of 120–1000 m (D. Kock pers. comm., Burgess *et al.* 2000a). Holotype was collected over Mukanda R. in the Shimba Hills, in open country interspersed with patches of forest (Bergmans 1997). Has not been recorded from East African savannas, suggesting a close association with forest (Burgess *et al.* 2000a, b). The specimen from Zimbabwe was collected in forest at the southern end of the Chimanimani Mts (Bergmans 1997).

Abundance Between one and seven individuals were mist-netted from each of six coastal forests in a survey of 16 Tanzanian coastal forests (Cockle *et al.* 1998), making it the most commonly captured fruit bat after *Epomophorus wahlbergi*. This suggests that it may be fairly common locally in suitable forests in Tanzania and SE Kenya.

Myonycteris relicta

Remarks A pregnant ♀ was collected in Nov, and a lactating ♀ and two subadult specimens were collected in Feb (SMF, D. Kock unpubl.). Nothing else is known about this species.

Conservation IUCN Category: Vulnerable.

Major threat: the coastal, Eastern Arc and Zimbabwean forest habitats of this species are subject to intense human pressure and are fragmenting.

Myonycteris torquata LITTLE COLLARED FRUIT BAT

Fr. Petite myonctère; Ger. Kleiner Halskrausen-Flughund

Myonycteris torquata (Dobson, 1878). Cat. Chiroptera Brit. Mus., p. 71, 76. Northern Angola, restricted to area of Golungo Alto by Crawford-Cabral (1986).

Taxonomy Originally *Cynonycteris torquata*. Placed in subgenus *Myonycteris* by some authors, but see Genus *Myonycteris*. Synonyms: *collaris*, *leptodon*, *wroughtoni*. Subspecies: none. Chromosome number (Cameroon, Gabon): $2n = 36$; $aFN = 66$ (Haiduk *et al.* 1981, Primus *et al.* 2006).

Description Small fruit bat with no basal ear-patches; no white markings on head; no epaulettes; no mantle; ♂♂ with ruff of stiff hairs; interfemoral membrane entirely covered by pelage; six lower cheekteeth; FA: 56–67 mm. Sexes similar except for ruff. Pelage dense, silky; extending half to two-thirds of way along forearm and marginally onto wing, along leg (but not as far as ankle) and over the entire interfemoral membrane; mid-dorsal hairs 6–7 mm. Dorsal pelage variable, rich dark rusty-brown to medium yellowish-brown, head, neck and shoulders usually paler and greyer: hairs unicoloured or with pale brownish-grey at base. No epaulette or white marking on shoulder. Ventral pelage slightly paler than dorsal pelage, medium brown to greyish-brown or pale grey. Juveniles darker than adults. Adults and juveniles of both sexes with a pronounced woolly throat ruff; adult ♂♂ with ruff of dense, coarse, brushy hairs, on chin, throat and upper chest, which are seasonally stained yellow-orange by oily secretions from underlying glands. Head without markings; muzzle moderately long and stout; cheeks only slightly expansible; lips thin and smooth. Ears dark brown with somewhat pointed tip. Palate usually with seven thick ridges, 1–3 undivided, 4–5 divided by narrow medial gaps (Figure 49a) but some variations are known (De Vree 1971, Bergmans 1976). Wing-membranes dark brown; attaching to second toe. Toes ‘webbed’ to middle of first phalanges or a little less.

Skull (Figures 46b and e, and 49c) short and delicate for an African fruit bat. Rostrum of medium relative length (ca. 34–35% of GLS). Dentition comparatively weak (cf. *M. relicta*) and simple; one or two lower incisors on each side; P^1 , M^2 and M_2 strongly reduced; M_3 usually present (cf. *M. relicta*) (Bergmans 1980, 1997). Posterior upper premolar (P^4) and first upper molar (M^1) oblong and subrectangular in occlusal outline, with longitudinal axes parallel to the line of the toothrow (Rosevear 1965). Dental formula usually $2^{132}/_{2133} = 34$ or $2^{132}/_{1133} = 32$, but other variations are known.

Geographic Variation No subspecies recognized by Bergmans (1976). There is some geographic variation in size with the smallest form (formerly *M. torquata*) in Cameroon, W Congo Basin and Angola, the largest form (formerly *M. wroughtoni*) in NE DR Congo and Uganda, and an intermediate form (formerly *M. leptodon*) west of the Niger R. (Bergmans, 1976).

Similar Species Four other African mainland species of fruit bats are small to medium-sized (FA: 56–107 mm) with no basal ear-patches and no other white or pale markings on the head:

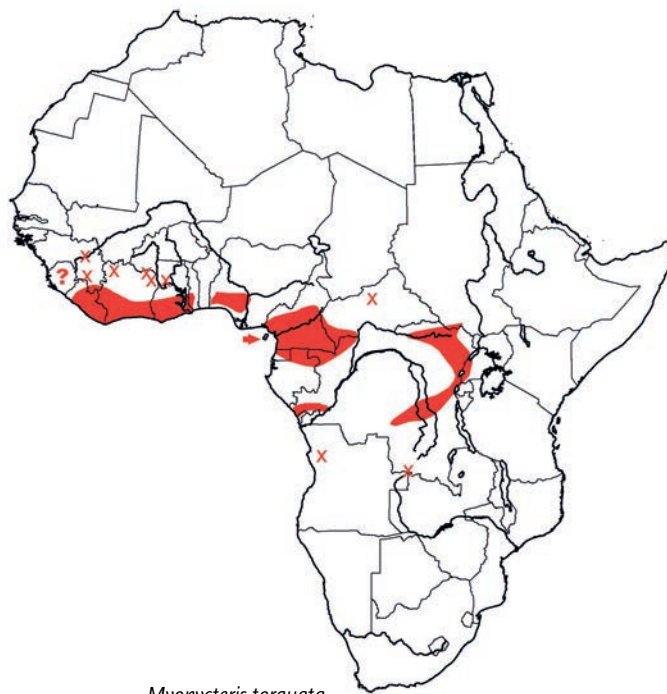

Myonycteris relicta. Usually smaller (FA: 65–75 mm; GLS: 35.5–39.2 mm). Interfemoral membrane with pelage only near legs. Five lower cheekteeth on each side.

Lissonycteris angolensis. Larger (FA: 68–90 mm). Tibia with pelage extending to ankle. Skull with premaxillae fused; posterior upper premolar and first upper molar squarish (occlusal view). Roosts in caves. More docile when handled.

Rousettus (2 spp.). Larger (FA: 82–106 mm). No ruff of coarse hairs.

Distribution Endemic to Africa. Recorded mainly from the Rainforest and Afromontane–Afroalpine BZs and the Rainforest–Savanna Mosaic, with marginal records in the Guinea Savanna and Zambezan Woodland BZs. Recorded disjunctly from Sierra Leone and Guinea to W Uganda and southwards to N Angola and S DR Congo, but absent from most of the Congolian rainforest. Also Bioko I. Recorded up to 1350 m. The exact locality of the specimen from Sierra Leone (the type locality of the form *leptodon*) is not known. Also recorded from Beletta Forest, Ethiopia, by Lavrenchenko *et al.* (2004): not mapped.

Habitat In central part of its distribution, most consistently associated with lowland rainforest, and appears to be most abundant in the canopy stratum (Cosson 1995). In West Africa, absent from savanna habitats in dry season (Jan–Apr), but penetrates into moist Rainforest–Savanna Mosaic and drier Guinea Savanna BZ in early wet season (Apr–May).

Myonycteris torquata

Abundance Various described as rare, uncommon and very common, depending on site, date and collector. Local abundance probably reflects changes in vertical stratification and seasonal migrations. In both Rainforest–Savanna Mosaic and Guinea Savanna BZ in Côte d'Ivoire, captures show a clear bimodal distribution with peaks in May–Jun and Nov–Dec, probably representing seasonal expansion from forest into savannas (Thomas 1983). Becomes the most common species in the Rainforest–Savanna Mosaic in the wet season (May–Jun).

Adaptations Very little is known. Flight 'has been described as slow and feeble' (Kingdon 1974). By day, one was found hanging from the branch of a *Combretum* tree, ca. 2 m above ground, directly exposed to the sunlight (Verschuren 1957), and there are two records of individuals hanging in bushes by day (Lang & Chapin 1917b, Rosevear 1965). Seasonal movements made by this fruit bat are described below (see Reproduction and Population Structure).

Foraging and Food Frugivorous. Little known about foraging behaviour and movements, but individuals captured at edge of gallery forest in Rainforest–Savanna Mosaic defecated *Solanum* seeds apparently from patches located several kilometres distant, suggesting wide foraging movements within single nights. Lack of any recaptures of banded individuals also suggests extensive movements. Has been described as a generalist, accepting a variety of soft fruits in captivity. Known to feed on figs *Ficus* and fruits of *Musa*, *Adenia*, *Solanum* and *Musanga* (Marshall 1985). The only systematic study of diet is from Guinea Savanna habitat where bitter *Solanum verbascifolium* fruits constitute 90% of diet (Thomas 1982). Apparently will visit flowers seasonally, as pollen (*Ceiba pentandra*?) was found on fur in Dec in Guinea Savanna. In captivity, the mean \pm S.D. nightly consumption of food (fruit) by ♂♂ was 50.0 ± 0.7 g ($n = 3$) and by ♀♀ was 55.5 ± 1.4 g ($n = 2$); mean consumption per unit body weight was $1.09 \text{ g/g}^{\text{bwt}}$; mean through-put time was 28 ± 12 min, and the percentage dry weight assimilated was 86% (Wolton *et al.* 1982).

Social and Reproductive Behaviour An adult ♂ was found roosting singly (Verschuren 1957), and a ♀ was found roosting with a half-grown young ♀ (Lang & Chapin 1917b). No other information.

Reproduction and Population Structure Litter-size: one ($n = 13$) (Jeffrey 1975). In Côte d'Ivoire, and also in Gabon, the reproductive chronology appears to be seasonal bimodal polyoestry. In Côte d'Ivoire (see below), births probably occur in Feb–Mar and ca. six months later in Aug–Sep (as in *Micropteropus pusillus*) – this is based on the observation that 87% of ♀♀ at Lamto were palpably pregnant with small embryos in May–Jun, and 100% of parous ♀♀ at Taï N. P. ($n = 26$) were pregnant with small fetuses in Nov (Thomas 1983). Near the Equator in Gabon, births occur Dec–Jan and in Jun (Brosset 1966). Length of gestation and lactation, and the timing of oestrus and mating are not known at either locality.

Myonycteris torquata is remarkable for sex- and age-related seasonal movements in Côte d'Ivoire, elucidated from capture numbers at Taï N. P. (05° 30' N; Rainforest BZ), Lamto (06° 13' N; Rainforest–Savanna Mosaic) and Wango Fitini (09° 50' N, Guinea Savanna BZ) (Thomas 1983). During the dry season (Nov–Mar), they are common in the Rainforest BZ and not captured in the Rainforest–Savanna Mosaic nor in the Guinea Savanna BZ. At the onset of the wet season (Apr–May), ♂♂, and to a lesser extent ♀♀, expand northwards into savanna habitats in the Rainforest–Savanna Mosaic, creating a peak in population numbers at Lamto in May–Jun. Only ca. 75% of these ♂♂ are mature and have throat ruffs, and ca. 87% of the ♀♀ are pregnant. All of the ♀♀ apparently then return to the rainforest in time to give birth later in the wet season (Aug–Sep). In contrast, at least some of the ♂♂ follow the inter-tropical front (and the rains) further northwards into the Guinea Savanna BZ, reaching Wango Fitini, for example, during the wettest months at that latitude. While in the north, testicular growth occurs in all of the ♂♂, and an oily exudate develops on the throat ruff. On the return journey, they pass through the Rainforest–Savanna Mosaic in Oct–Dec and create a second 'males only' peak in population numbers. These ♂♂ then return to the Rainforest BZ in time for the Feb–Mar births and presumably participate in the following mating season (having been absent from the Rainforest during the mating season that followed the Aug–Sep births).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

GENUS *Nanonycteris*

Veldkamp's Dwarf Epauletted Fruit Bat

Nanonycteris Matschie, 1899. Die Fledermäuse des Berliner Museums für Naturkunde. I. Megachiroptera, pp. 36, 58.

Type species: *Epomophorus veldkampii* Jentink, 1888.

Nanonycteris is a monotypic genus, endemic to Africa, and found in western tropical Africa from Guinea to Central African Republic, mainly in the Rainforest BZ and the adjacent Northern Rainforest–Savanna Mosaic. Diagnostic characters: white basal ear-patches but no other white markings on head; FA: 46–54 mm; ♂♂ on average smaller than ♀♀; epaulettes in adult ♂♂, muzzle slender and simple; interfemoral membrane well developed and with calcars; four thick interdental palatal ridges and 8–9 thin ridges of which only the posterior group is narrowly divided; postdental bony palate very short and broad, its lateral margins more or less parallel; C–M¹: 6.8–7.7 mm; usually three upper and five lower cheekteeth (very occasionally four upper cheekteeth) (Table 11, p. 228). Selected characters of *Nanonycteris veldkampii* are illustrated in Figure 50.

Nanonycteris was described as a subgenus of *Epomophorus*, but raised to generic status by Andersen (1912a). *Nanonycteris* was placed in the epomophorine section of Andersen (1912a); he considered it to be closely related to *Scotonycteris* and *Casinycteris*, and grouped these genera in the ‘*Nanonycteris* branch’. Bergmans (1997) classified *Nanonycteris* as a member of the tribe Epomophorini within the subfamily Epomophorinae. This is supported by recent phylogenetic analyses in which *Nanonycteris*

grouped with other epomophorine genera, i.e. *Epomophorus*, *Epomops*, *Hypsignathus* and *Micropteropus* (Springer *et al.* 1995, Jones *et al.* 2002). However, Romagnoli & Springer (2000) found *Nanonycteris* as a basal member of a clade including the genera mentioned above plus *Scotonycteris* and *Casinycteris*. According to their results, *Nanonycteris* and *Plerotes* would form the basal stem of an extended epomophorine clade, i.e. similar to the arrangement of Andersen (1912a) except that *Scotonycteris* and *Casinycteris* would represent a derived epomophorine clade.

The single species is *Nanonycteris veldkampii*.

Nanonycteris veldkampii VELDKAMP'S DWARF EPAULETTED FRUIT BAT

Fr. Roussette naine de Veldkamp; Ger. Veldkamps Zwergflughund

Nanonycteris veldkampii (Jentink, 1888). Notes Leyd. Mus. 10: 51. Buluma, Fisherman L., Liberia.

Taxonomy Originally *Epomophorus veldkampii*. Synonyms: none. Sometimes spelled *N. veldkampii* but the correct spelling is *veldkampii*. Chromosome number: not known.

Description Very small fruit bat with anterior and posterior basal ear-patches but no other white markings on head; epaulettes on adult ♂♂; 8–9 thick or partly thick palatal ridges; FA: 46–54 mm. Not easily distinguished from *Micropteropus pusillus* except by palatal ridges. Sexes similar in colour; ♂♂, on average, with slightly smaller body measurements. Pelage dense, soft; mid-dorsal hairs 6–7 mm. Dorsal pelage brown, reddish-brown, greyish-brown to pale brown. Ventral pelage much paler. Adult ♂♂ with a white or yellowish epaulette on each shoulder (retracted into pouch except when displayed; sometimes stained yellow by pollen in dry season); ♀♀ with patch of soft, off-white hairs on each shoulder. Head with anterior and posterior basal ear-patches; muzzle moderately short, very slender, evenly tapering; lips slightly expansible (more wrinkled in adult ♂♂). Ears dark brown, naked, narrow. Eyes large, yellowish-brown. Palate with three narrow but thick ridges (the first two undivided, the third usually undivided, rarely notched, or very narrowly divided), 5–6 ridges, which are thick in middle, notched anteriorly or divided by narrow gap, and have serrated, backward-directed lateral arms, and 3–4 thin ridges (Figure 50). Wing-membranes dark brown; attaching to second toe. No visible tail.

Skull (Figure 50) short and delicate for an African fruit bat. Braincase rounded and deflected against rostrum. Rostrum of medium relative length (34–37% of GLS) and slender. Zygomatic arches slender. Postdental palate very broad, about same width as distance between upper molars. Upper toothrow short, not nearly reaching ventral margin of orbital cavity. Dentition comparatively weak. Dental formula $^{2121}_{2132} = 28$ (P¹ present very occasionally).

Geographic Variation None.

Similar Species Thirteen other species of fruit bats have simple muzzles; basal ear-patches but no other markings on head; adult ♂♂ with epaulettes; three upper and five lower cheekteeth:

Micropteropus pusillus. Six palatal ridges; muzzle broader at tip; lips more expansible. Sympatric in West Africa, Cameroon, Central African Republic.

M. intermedius. Six palatal ridges. Not sympatric.

Epomophorus (8 spp.). Six thick palatal ridges.

Epomops (3 spp.). Three or five thick palatal ridges. Larger (FA: >76 mm).

Distribution Endemic to Africa. Recorded from the Guinea Savanna BZ, Northern Rainforest–Savanna Mosaic, Rainforest BZ (West and West Central Regions) and Afromontane–Afroalpine BZ. Known from Guinea and Sierra Leone to C and SW Cameroon, and Bangui in Central African Republic. Additional specimens from the

*Nanonycteris veldkampii*

apparent gap between C Cameroon and Central African Republic are necessary to establish a more complete picture of the eastern part of the distribution.

Habitat This migratory species occupies a wide range of habitats (see also Adaptations). In Rainforest BZ, found mainly in farmland, small-scale plantations and secondary forest; also found in coastal and montane forest and (rarely) in undisturbed lowland rainforest (Coe 1975, Jeffrey 1975, Bergmans 1989). Has also been found in mangroves. Within Guinea Savanna BZ and Rainforest–Savanna Mosaic, mainly found where gallery and relict forests are present (Van Orshoven & Van Bree 1968, Marshall & McWilliam 1982, J. Fahr unpubl.). Not yet recorded from wettest parts of S Liberia and SW Côte d'Ivoire; rarely recorded from Dahomey Gap. Mostly found at lower altitudes, but found up to 1200 m on Mt Nimba, Liberia (Verschuren 1976).

Abundance Locally rare to very common, depending on habitat and season. In Jul–Aug (wet season), more common than *Micropteropus pusillus* and *Epomophorus gambianus* in the Guinea Savanna BZ at Mole N. P., Ghana (245 of 379 individuals; Marshall & McWilliam 1982). In the Guinea Savanna BZ of Comoé N. P., Côte d'Ivoire, comprised 22% of fruit bats captured in wet season (n = 1528) and was the second most abundant species (after *M. pusillus*) in a community of nine species of fruit bats (J. Fahr unpubl.). In *Borassus*-savanna with gallery forest at Lamto, Côte d'Ivoire, comprised only 1.7% of fruit bats captured in wet season (n = 2071) and was the seventh most abundant species in a community of nine species of fruit bats (Thomas 1982). In undisturbed rainforest of Tai N. P., Côte d'Ivoire, comprised only 0.6% of fruit bats

captured throughout year ($n = 1216$; J. Fahr & S. Pettersson unpubl.); rarest species in community of eight species of fruit bats. However, along disturbed fringes of Tai N. P. during dry season, comprised 9.9–29.4% of fruit bats captured (Thomas 1982, T. Gordon pers. comm.). At Mt Nimba, comprised 16.5–25.3% of fruit bats captured; either the most or second most abundant species (after *Myonycteris torquata*) in a community of ten species of fruit bats if study period included the dry season (Coe 1975, Verschuren 1976, A. Forbes-Watson in Wolton *et al.* 1982). In contrast, completely absent during wet season (Wolton *et al.* 1982).

Adaptations Flight faster and more agile than that of *E. gambianus* (Baker & Harris 1957). Day-roosts mostly unknown. Local people of Mt Nimba region, Liberia, report roosting in old barbet (Capitonidae) and woodpecker (Picidae) holes, and one individual was found in such a situation in a newly felled tree (Coe 1975). Seasonally migratory (Thomas 1982, 1983). During dry season (Oct–Feb), resident in Rainforest BZ of West Africa (Coe 1975, Wolton *et al.* 1982, J. Fahr & S. Pettersson unpubl.). At onset of wet season (Mar–Apr), both sexes migrate northwards, inhabiting the Rainforest–Savanna Mosaic (e.g. Lamto, Côte d’Ivoire) in Mar–Jun with a peak in catch-rate in Apr, and the Guinea Savanna BZ (e.g. Wango Fitini, S Comoe N. P.) in Apr–Jul with peak in catch-rate in May (Thomas 1983, J. Fahr unpubl.). In the Sudan Savanna further north (e.g. Wango Fitini, Mole N. P.), recorded during Apr, May, Jul and Aug (Marshall & McWilliam 1982, Thomas 1982, J. Fahr unpubl.). At end of wet season in the north, all but a few return to Rainforest BZ via the Rainforest–Savanna Mosaic, where they have been recorded in Aug–Jan with a second peak in catch-rate in Oct (Thomas 1982). Small numbers of this species remain in the Guinea Savanna BZ (Comoe N. P.) between Oct and Dec (J. Fahr & N. Ebigo unpubl.). Possibly the temporal and spatial pattern of the southward migration is more diffuse. During this time, many trees such as *Adansonia digitata*, *Ceiba pentandra*, *Kigelia africana* and *Parkia biglobosa* are flowering and are exploited by this bat (see below). The distance between rainforest and savanna locality records indicates a round-trip migration of 300–1100 km, depending on the width of the respective vegetation zones in a given region (Thomas 1982, 1983, J. Fahr unpubl.). Preliminary data from Ghana suggest that this bat also moves south during the wet season where suitable habitat is available (J. Fahr unpubl.). In the savanna-dominated Accra Plains south of the rainforest zone, it has been recorded during Mar, Jul, Aug and Sep. In this area, movements might be rather local between the rainforest and adjacent coastal savannas.

Foraging and Food Feeds on figs, fruits, nectar and pollen. Capture data, using mist-nets 0–25 m above ground in Comoe N. P., suggest preferential foraging fairly near ground and comparatively close to vegetation (median capture height 4.9 [0.9–23.6] m, $n = 332$) (J. Fahr unpubl.). Activity, based on frequency of captures, is fairly continuous throughout night with three indistinct peaks (around 20:00h, 23:00h and 01:00h), and least activity around 03:00h. In Mole N. P., Ghana, sometimes forages later than *Micropteropus pusillus*, and has major activity between 22:00h and 02:30h (Marshall & McWilliam 1982). Also observed to visit flowering *Parkia* trees later than *E. gambianus*, and to harass this larger species which then usually flew away (Baker & Harris 1957). However, *N. veldkampii* (and/or *M. pusillus*) sometimes visits flowering or fruiting trees

in mixed-species flocks of 15–20 bats, including *E. gambianus* and/or *M. pusillus*, but the arrival and departure of the different species was not highly synchronized (Marshall & McWilliam 1982). Diet includes fruits, nectar and pollen. Probably better adapted to nectarivory than *M. pusillus* (Marshall & McWilliam 1982) but not entirely nectarivorous as assumed by Wilson (1973). Flowering trees visited include *Kigelia* sp., *Adansonia digitata*, *Ceiba pentandra*, *Eperua falcata*, *Maranthes polyandra*, *Parkia biglobosa* and *Protea elliptica* (Baker & Harris 1957, Harris & Baker 1959, Lock & Marshall 1976, Lack 1978, Dobat & Peikert-Holle 1985). Marshall & McWilliam (1982) questioned some of the identifications based on observations of flying bats because *N. veldkampii* is easily confused with *M. pusillus*. Baker & Harris (1957) and Harris & Baker (1959) made detailed observations and photographed the visits to the pendulous inflorescences of *Parkia biglobosa*: individuals approached an inflorescence, clasped it with the wings and licked the nectar while holding on with their thumbs; visits lasted 1–30 sec. In contrast, when taking nectar from *Ceiba pentandra*, they land on the branches, crawl over them and lap from flowers as they encounter them (Baker & Harris 1959). During peak flowering of *C. pentandra* (Nov–Dec) these bats are stained bright yellow by the pollen, mistakenly attributed to a particular fruit by Coe (1975). Also feeds on figs *Ficus umbellata* and fruits of *Vitellaria paradoxa*, *Cola cordifolia*, *Solanum erianthum*, *Mangifera indica*, *Carica papaya*, *Psidium guajava* and *Musa* spp. (Baker & Harris 1957, Ayensu 1974, Coe 1975, Marshall & McWilliam 1982, Thomas 1982, J. Fahr unpubl.). Captive bats ingest 1–2 times their body weight per day, and gain ca. 1.5 g between dusk and dawn (Coe 1975, Marshall & McWilliam 1982). According to Coe (1975), single bats consumed much more in captivity than groups of bats although all were fed *ad libitum*.

Social and Reproductive Behaviour Males probably call during the night to attract ♀♀ (as do other epauletted fruit bats). Monotonously repeated high-pitched calls were heard frequently in gallery forests and relict forests in Comoe N. P. The unseen animals appeared to call solitarily, from widely spaced perches high in the trees. Temporarily caged ♂♂ responded by making identical calls, so the unseen callers were probably also *N. veldkampii*. Males presumably display their epaulettes during courtship as do other epauletted fruit bats.

Reproduction and Population Structure Litter-size: one. Reproductive chronology uncertain but records from West Africa (Guinea, Côte d’Ivoire, Liberia and Ghana combined) include evidence of polyoestry and some evidence that ♀♀ are not in close reproductive synchrony, which suggests that births occur either aseasonally or during fairly extended seasons. Several sympatric species of fruit bats exemplify polyoestry at these localities, but none are known to have extended seasonal or aseasonal parturition. The simultaneous occurrence of lactation and pregnancy has been observed (Thomas 1982, J. Fahr unpubl.), indicating that polyoestry and postpartum oestrus occur in at least some ♀♀. Percentages of pregnant ♀♀ exceeding 50% of all ♀♀ captured (including subadults) have been reported in Nov–Dec (75%, $n = 13$; Coe 1975) and also in May (55%, $n = 87$, J. Fahr unpubl.), indicating that many births occur during at least two seasons. Furthermore, in Jul–Aug, almost 50% of the ♀♀ were either pregnant or lactating while the remainder were immature ($n = 49$; Marshall & McWilliam

1982), which also indicates births during more than one season. However, pregnancies have been reported in all months except Sep (for which there are no data), and lactation has been observed during all months except Sep and Mar (Van Orshoven & Van Bree 1968, Coe 1975, Jeffrey 1975, Verschuren 1976, Marshall & McWilliam 1982, Thomas 1982, Lim & Van Coeverden de Groot 1997, J. Fahr unpubl.). These observations indicate a lack of close reproductive synchrony, but whether the chronology is aseasonal or extended seasonal polyoestry remains to be determined and, although ♀♀ are not likely to have more than two litters/year, this and the length of gestation are not yet known.

When capture data for a whole year are combined, the ratio of ♂♂ to ♀♀ is close to unity, e.g. 1 : 1.3 (n = 342) in Comoé N. P., Côte d'Ivoire (J. Fahr unpubl.). Contrary to Thomas (1982), there is at least some partial segregation of the sexes during migration. In Comoé N. P., captures were dominated by ♀♀ between Mar and Jun and by ♂♂ during Jul, Oct and Dec. Between Dec and Mar, Verschuren (1976) found a ratio of 1 ♂ : 3.2 ♀ (n = 42) at Mt Nimba, Liberia. According to Wolton *et al.* (1982), ♀♀ arrive on their southward migration one month later in the rainforest zone than ♂♂.

Predators, Parasites and Diseases Ectoparasites include a mite *Binuncus (Binuncus) myonycteris* (Acari: Myobiidae) (Uchikawa 1986).

Conservation IUCN Category: Least Concern.

Large-scale degradation of habitat might disrupt pattern of migration.

GENUS *Plerotes*

Anchieta's Broad-faced Fruit Bat

Plerotes K. Andersen, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 97. Type species: *Epomophorus anchietae* Seabra, 1900.

Plerotes is a monotypic genus, endemic to Africa. Diagnostic characters: white basal ear-patches (sometimes inconspicuous); no other white markings on the head; FA: 47–53 mm; adult ♂♂ without epaulettes; muzzle simple; interfemoral membrane greatly reduced; calcars absent; four curved undivided palatal ridges followed

by 4–5 serrated ridges, which are more or less divided; four or five upper cheekteeth and five or six lower cheekteeth (Table 11, p. 228). Selected characters of *Plerotes anchietae* are illustrated in Figure 51.

Plerotes was placed in the *Epomophorus* section of Andersen (1912a) and *Epomops* was considered to be its nearest ally (Andersen 1910,

Figure 51. *Plerotes anchietae*. Palatal ridges drawn from skull with dried soft palatal tissue *in situ* (BMNH 43.45). Skull (neotype, immature ♀) (based on Bergmans 1982 with permission of the author): the ventral view also shows dried soft palate *in situ* and Bergman (1982) notes that it masks the margin of the post-dental palate.

1912a). Cladistic analyses of 33 morphological characters placed *Plerotes* in the same clade as *Rousettus* and *Lissonycteris*, suggesting that it should be excluded from the *Epomophorus* section (Springer *et al.* 1995). Bergmans (1997) retained *Plerotes* within Epomophorinae, Tribe Plerotini, but later (based on Springer *et al.* 1995 and new information from Kock *et al.* 1998a) W. Bergmans (pers. comm.) expressed uncertainty about his placement of *Plerotes* within the Epomophorinae. The more recent cladistic analyses of Álvarez *et al.* (1999), Giannini & Simmons (2003) and others have not included *Plerotes* in their analyses, but N. P. Giannini & N. B. Simmons (pers. comm.) have unpublished data suggesting that *Plerotes* is better

placed in Epomophorinae than in Rousettinae.

The single species of *Plerotes* was originally assigned to *Epomophorus*, and then to *Epomops*. Andersen (1910) raised it to generic status on the basis of 11 characters of its skull and dentition that differentiate it from *Epomops*. The 11 characters are listed and discussed by Bergmans (1989). Since Andersen, the generic status of *Plerotes* has not been disputed.

The single species is *Plerotes anchietae*.

Meredith Happold

Plerotes anchietae ANCHIETA'S BROAD-FACED FRUIT BAT (BENGUELA FRUIT BAT)

Fr. Plérote d'Anchieta; Ger. Anchietas Breitgesicht-Flughund

Plerotes anchietae (Seabra, 1900). J. Sci. Math. Phys. Nat. Lisboa, ser. 2, 6: 116. Galanga, Benguela, Angola.

Taxonomy Originally *Epomophorus anchietae*. Synonyms: none. Chromosome number: not known.

Description Very small, pale greyish-brown fruit bat with yellowish-white moustache and beard, and posterior whitish basal ear-patches (sometimes inconspicuous) but no other white markings on head; no epaulettes; greatly reduced interfemoral membrane; four or five upper cheekteeth. Only 11 specimens known. Sexes apparently similar. Pelage soft; mid-dorsal hairs ca. 8 mm. Dorsal pelage uniformly pale greyish-brown; hairs pale creamy-brown with darker, greyish-brown at tip. Ventral pelage pale creamy-brown. No mantle or collar of contrasting pelage. No epaulettes, but both sexes with white spot on each shoulder and a whitish patch (sometimes inconspicuous) at the posterior base of each ear. Head with relatively broad muzzle. Eyes large, narrowly ringed with reddish-brown pelage and with band of reddish-brown pelage from each eye-ring to the nostril. Moustache of stiff yellowish-white hairs on upper lip, and beard of similar hairs on chin. According to Seabra (in Harrison 1960), there are cheek-pouches on each side of the muzzle surrounding the eye, but there is no evidence that these are sound-amplifying pouches as stated by Kingdon (1997). In contrast, Kock (pers. comm.) did not find pouches around the eyes of an adult male specimen, and Kock *et al.* (1998a) noted that the lips and cheeks do not stretch to form cheek-pouches, and that the lips are smooth. Ears brown. Palatal ridges simple; 1–4 curved and undivided, 5–8 serrated and more or less divided (Figure 51). Tongue with filiform papillae covering the tip (as in *Megaloglossus woermanni*), but the papillae are rather short (cf. greatly elongated in *Megaloglossus*) (Harrison 1960) (Figure 35c). Wing-membranes brown; attaching to second toe. No tail. Interfemoral membrane, uniquely, no more than a narrow flange; no calcars.

Skull (Figure 51) short and delicate for an African fruit bat. Rostrum of medium relative length and relatively broad. Dentition weak. Incisors minute; one or two upper incisors on each side; original function probably lost. Premolars long and narrow; anterior premolar (P^1) present but rudimentary. Molars simple, without cusps; M^2 , M_2 and M_3 rudimentary or absent. Cheekteeth $4/6$, $4/5$ or $5/6$ (some cheekteeth are prone to being deciduous), therefore dental formula very variable – maximally $2^{132}/_{2133} = 34$.

Geographic Variation None recorded. Apparently inhabits two separate areas, so intra-specific variation is likely (Bergmans 1989).

Similar Species None. Other fruit bats of similar size lack reddish-brown markings on the head, do not have a white moustache and beard, and do not have interfemoral membranes which are reduced to a very narrow flange.

Distribution Endemic to Africa. Appears to have a disjunct distribution in the Zambezian Woodland BZ and nearby Afromontane–Afroalpine BZ. Western range in Angola; eastern range in S DR Congo, N Zambia and Malawi. Map based on Bergmans (1989).

Habitat Most records are from wetter miombo woodland dominated by *Brachystegia*, *Julbernardia* and *Isoberlinia*, but some are from mosaics of the above with dry evergreen forest, and

Plerotes anchietae

afromontane vegetation. Recorded from 1000 to 2000 m, which suggests a preference for montane and sub-montane habitats, but this needs confirmation.

Abundance Uncertain. Very rarely collected (only 11 specimens).

Remarks Nothing is known about the habits of this species. The diet is not known (*contra* Kingdon 1997). The simplicity of the palatal ridges, the presence of filiform papillae on the tip of the tongue, the delicacy of the skull and the weakness of the dentition suggest a diet of pollen and perhaps also nectar, and the moustache and beard of stiff hairs perhaps serve to transport pollen. However, the tongue is not particularly long nor as extensible as it is in nectar-feeding fruit bats such as *Megaloglossus* (Harrison 1960). Based on the short tongue and Seabra's indication that cheek-pouches are present, Harrison (1960) concluded that the diet of *Plerotes* is unlikely to be solely nectar, and he suggested that it might consist partly of soft fruit and partly of pollens. One specimen (BMNH 63.45) was caught at a fruiting *Parinari curassifolia* tree, although it is not known whether it was feeding on the fruit. Consequently, the diet of *P. anchietae* is an intriguing mystery, which should be investigated if individuals are captured in the future.

Conservation IUCN Category: Data Deficient.

Major threat: deforestation.

GENUS *Pteropus*

Flying-foxes

Pteropus Brisson, 1762. Regnum Animale, Ed. 2, pp. 13, 153. Type species: *Vespertilio vampirus niger* Kerr, 1792.

Pteropus seychellensis.

Pteropus is a polytypic genus with 65 species (Simmons 2005), the majority of which are found on islands in the Pacific and Indian Oceans. Two species occur on islands off the coast of East Africa. These species can be distinguished from other African fruit bats by the following characters: no white basal ear-patches; no white markings on the face; FA: 145–163 mm; dorsal pelage blackish-grey with a contrasting red or yellow mantle; no ruff of stiff hairs around the neck; five upper and six lower cheekteeth (Table 11, p. 228). The heads of the African species and craniodental characters of *P. voeltzkowi* are shown in Figure 52.

No species of *Pteropus* occurs on the African mainland, but *P. voeltzkowi* occurs on Pemba I. (where it is endemic), and a species currently considered to be *P. seychellensis comorensis* occurs on Mafia I. (and extraliminally in the Comoros). These species are considered closely related. Speciation is facilitated by the isolation of populations on islands, so it is not surprising that there is a high level of endemism on the islands of the W Indian Ocean: eight species (nine subspecies) on nine islands or clusters of islands. Five of these islands or island-clusters are inhabited by only one species but, currently or in the recent past, three islands (Comoros, Réunion, Mauritius) have two sympatric species, which shows that the process of speciation in *Pteropus* of the Indian Ocean took place long ago and that colonization of some of the islands has occurred more than once.

Flying-foxes are very large fruit bats. Those for which data are available have low aspect ratios and extremely high wing-loadings (Norberg & Rayner 1987). Although their flight can appear laboured and not particularly fast, some species fly 40–60 km from roost to feeding-ground and back again in one night, and satellite-tracking of two individuals showed that some *Pteropus poliocephalus* make migratory round-trip journeys of at least 2000 km along the east coast of Australia (Tidemann & Nelson 2004). Furthermore, one Australian flying-fox flew ca. 2000 km to New Zealand (Daniel 1975). At least one species, *Pteropus poliocephalus* in coastal Australia, uses prevailing winds for assistance (Tidemann & Nelson 2004), and some species have become specialist gliders, which soar on updrafts and then glide most of the way to their feeding-grounds (Norberg *et al.* 2000). Some flying-foxes land gracefully by flying slowly over

Figure 52. African *Pteropus*. (a) Head of *P. seychellensis comorensis*. (b) Head of *P. voeltzkowi*. (c), (d) and (e) Skull of *Pteropus voeltzkowi* (BMNH 55.163, adult ♂). The minute anterior upper premolar is absent in this specimen: in the ventral view, its position is shown by dotted circle between the canine and second premolar on each side.

a perch, grasping it with the hindfeet and then toppling down into the hanging position. Others often make crash-landings into foliage or onto bunches of fruit or flowers. However, unlike most African fruit bats, they are very agile climbers. The fingers fold the wing-membranes close to the forearms, which then resemble long legs with a large hook (the clawed thumb) at the end. Flying-foxes swing along under thin branches, holding on with the claws of the thumbs and toes, and moving the wings in alternation. They climb, head first, up or down vertical surfaces in a similar fashion. Flying-foxes also use their forearms and thumbs to pull fruits or flowers within reach and to manipulate food while eating. Some species on islands will often cross water to forage on other islands, and some occasionally swim in the sea albeit probably only after accidentally falling in (Bergmans 1978).

Flying-foxes inhabit forests and swamps, and most are found near coasts. Some species are found on continents and large islands; others (including *P. seychellensis comorensis* and *P. voeltzkowi*) are small-island specialists, which are often found on small islands near the coasts of much larger islands or continents. Flying-foxes feed mainly on the juices of soft fruits: pulp is crushed in the mouth and the juice swallowed; fibre and seeds are discarded. They also chew flowers to obtain juices and pollen. Most species roost in groups, ranging from about 20 to several hundreds of thousands, and their roosting-sites are usually referred to as camps. Flying-foxes hang freely from the branches, often choosing trees that rise above the forest canopy. Colonies of roosting flying-foxes may be divided into family groups,

territorial ♂♂ with harems, juvenile packs and/or guard groups that roost on the periphery and give warning of intruders. Vocal communication is sophisticated: *P. polycephalus* (in Australia) has more than 20 situation-specific calls (Churchill 1998). Some roosts or 'camps' may be used for many decades, and they are often remote from the feeding-grounds. Most flying-foxes are nocturnal, but some island species are partly diurnal. Most species have one young/litter and one litter/year with births occurring seasonally and in synchrony (Pierson & Rainey 1992).

The colonization, by *Pteropus*, of the African off-shore islands and the other islands in the W Indian Ocean has been discussed by authors including Kingdon (1974), Meirte (1984) and Bergmans (1997). These authors agree that *Pteropus* colonized these islands from Asia but the details are controversial and, as yet, unresolved. The presence of flying-foxes on Pemba I. and Mafia I., but not on the mainland, has led to the conjecture that flying-foxes, spreading westwards from islands in the Indian Ocean, may not have been able to compete against the fruit-eating mammals on the African mainland. However, on Pemba I., *P. voeltzkowi* successfully co-exists with other fruit-eaters including three other fruit bats (*Eidolon helvum*, *Rousettus aegyptiacus*, *Epomophorus wahlbergi*), a monkey *Cercopithecus aethiops nesiotes* (now *Chlorocebus pygerythrus*) and a Greater Galago *Galago crassicaudatus agisymbanus* (now *Otolemur garnetti*) (Moreau & Pakenham 1940, Kingdon 1974). Another conjecture is that flying-foxes may have been too vulnerable to predators to survive on the mainland. However, Pemba I. has

several species of owls and falcons, a python and a monitor lizard and, on the mainland, other sorts of carnivores are not important predators of fruit bats. The majority of flying-foxes are island specialists, which led Kingdon (1974) to ask 'what is peculiar to islands that might eventually leave its mark on fruit bats which have adapted to living on them?' It has been suggested that *Pteropus* might depend on seawater as a source of salts, which would prevent them from inhabiting central parts of Africa (Kingdon 1990), but this does not explain why they do not live along coastal Africa (McNab & Armstrong 2001). Nevertheless, it is curious that the vast majority of species in this genus are restricted to coastal areas and small islands, and there are anecdotal reports of *Pteropus* flying out to sea, dipping their muzzles into the water and appearing to drink (Iudica & Bonaccorso 2003). It is not yet known if they can assimilate mineral salts from ingested seawater, but ascertaining this might lead to an explanation as to why most species live near the sea (Iudica & Bonaccorso 2003). The reproductive biology of 23 species of *Pteropus* was reviewed by Pierson & Rainey (1992); all

are monotocous and, for most species, the chronology is restricted seasonal monoestry; gestation is on average 5.5 months; young become volant at ca. three months and are weaned at 4–6 months; ♀♀ reach reproductive maturity at 1.5–2.0 years.

Pteropus was placed in the *Rousettus* section of Andersen (1912a), but was placed in the subfamily Pteropodinae (tribe Pteropodini) by Bergmans (1997) (see family profile). Andersen (1912a) divided the species into 17 groups of which only the *niger* group is represented in Africa. The African representatives are:

P. seychellensis comorensis. Mantle bright yellow or brownish-yellow; face with dark mask (Figure 52a). Mafia I. and extraliminally Comoros.

P. voeltzkowi. Mantle bright rusty-red; face without dark mask (Figure 52b). Pemba I. only.

Meredith Happold

Pteropus seychellensis SEYCHELLES FLYING-FOX

Fr. Grande roussette des Seychelles; Ger. Seychellen-Flugfuchs

Pteropus seychellensis Milne-Edwards, 1877. Bull. Sci. Soc. Philom. Paris, ser. 7, 2: 221. Marianne I., Seychelles.

Taxonomy Species-group: *niger* – with *P. rufus* (Madagascar), *P. voeltzkowi* (Pemba I. [Tanzania]), *P. aldabrensis* (Aldabra Atoll) and *P. niger* (Reunion and Mauritius) (Koopman 1994). Synonyms: *comorensis*. Two subspecies are recognized by Bergmans (1990): *P. s. seychellensis* in the Seychelles and *P. s. comorensis* on four islands (Grande Comore, Anjouan, Mohéli and Mayotte) in the Comoros, and Mafia I. (Tanzania). However, recent studies of *Pteropus* in the Western Indian Ocean (O'Brien *et al.* 2009, Chan *et al.* 2011) have indicated that paraphyly exists in members of the *Pteropus seychellensis* complex, but the taxonomy of *P. seychellensis* is still in a state of flux (S. Goodman pers. comm.). For this reason, the *Pteropus* on Mafia I. is referred to here as *P. s. comorensis*, and the remainder of this account refers to this taxon. Because information from Mafia I. is limited, some data from the Comoros are included. Chromosome number: not known.

Description Very large, dorsally blackish-brown fruit bat with conspicuous bright yellow, pale gold or brownish-yellow mantle; fox-like head with dark face-mask; no ear-patches; no white markings on head; no epaulettes. Sexes similar. Pelage dense; mid-dorsal hairs ca. 14 mm. Dorsal pelage: crown golden-yellow or brownish-yellow; nape with longer, coarser (especially in ♂♂), golden-yellow or rusty-yellow pelage forming the mantle; back and rump blackish-brown, sometimes with scattered pale grey hairs. Dorsal hairs yellow or blackish-brown. Ventral pelage: chin and throat dark brown merging into bright orange, rusty-yellow or bright rusty-brown on chest, merging into dark brown with pale yellow wash on belly and flanks. Hairs on belly and flanks dark brown with yellow at tip. Muzzle long and tapering, giving head its fox-like appearance; muzzle and anterior half of face dark brown contrasting with the posterior half, which is yellow (Figure 52a). Ears pointed, naked, very dark brown. Wing-membranes very dark brown; attaching to

second toe. Interfemoral membrane well developed; in centre ca. 15 mm deep. No tail.

Skull long and robust for an African fruit bat. Rostrum of medium relative length. Dental formula $2^{132}/_{2133} = 34$.

Geographic Variation Two subspecies are recognized (but see Taxonomy). Specimens of *P. s. comorensis* from Mafia I. have more grey in the dorsal pelage, but variation between populations here and in the Comoros needs further analysis (Bergmans 1990).

Similar Species Two other species of large African fruit bats have no basal ear-patches; no white markings on head; FA: >108 mm:

Pteropus voeltzkowi. Mantle rusty-brown ('red'); no dark face-mask. Pemba I. only.

Eidolon helvum. Dorsal pelage usually pale and yellowish, no mantle. Smaller (FA: 105–135 mm). Mainland and islands including Pemba I. and Mafia I.

Distribution Currently, *P. s. comorensis* is considered to occur on Mafia I. off the coast of Tanzania and, extraliminally, Comoros. Moreau & Pakenham (1940) suggested that immigrant Comorians possibly imported the fruit bats to Mafia I. from Comoros as a potential source of food.

Habitat *Pteropus s. comorensis* is a small-island specialist. Mafia I., area 622 km², lies ca. 20 km from the mainland. It is a recent continental island isolated in the Pleistocene (Moreau & Pakenham 1940). There are remnants of evergreen forest (once widespread), and East African coastal forest mosaic, mangroves, palms and swamps. No rivers, many pools. Wet season (85% of rainfall) Dec–May, but rain in all months. On Comoros, this fruit bat roosts

Pteropus seychellensis

between sea level and 720 m and utilizes lowland and agricultural areas to a greater extent than the sympatric *P. livingstonii*, which roosts at higher altitudes and is more dependent on primary upland forest (Trehwella *et al.* 2001).

Abundance No recent information for Mafia I. except that two camps were seen in Oct 1990 (N. Payne in Mickleburgh *et al.* 1992). Common in Comoros.

Adaptations Aspect ratio very low; wing-loading exceptionally high. Able to glide, but spends the majority of its flight-time flapping rather than gliding, and is less well adapted for soaring than *P. livingstonii* (Norberg *et al.* 2000). By day, hangs freely from branches of shaded trees including *Ceiba*, *Tamarindus* and *Casuarina*. In Comoros, camps are sited where topographical features such as ravines and volcanic craters give protection from high winds, facilitate thermoregulation, and create updraughts, which may help the bats gain height before they set off towards feeding-grounds, which may be 5 or more kilometres away (Cheke & Dahl 1981). Individuals urinate on their wings and fan themselves to achieve evaporative cooling. They leave their roosts early in the afternoon, probably to maximize the use of updraughts and gliding to reach distant feeding-grounds with minimal loss of energy and minimal production of heat generated by flapping the wings (Norberg *et al.* 2000). From the late afternoon until shortly after sunset, individuals have been observed flying a short distance out to sea and then flying down to dip their hind-quarters into the down-slope of incoming waves. The purpose of this behaviour is open to conjecture: possibly to obtain salts lacking in fruit. This complex manoeuvre was observed many times at close range and the bats were never seen to grasp anything with their hindfeet so it is unlikely that they were trawling fish or collecting floating fruits.

Foraging and Food Feeds on soft fruits, pollen, nectar and leaves (Mickleburgh *et al.* 1992, Trehwella *et al.* 2001). In Comoros,

individuals begin flying to feeding-grounds as early as mid-day, but most leave their roosts between 14:00h and 17:30h with a peak at 14:45h (Trehwella *et al.* 2001). They feed at intervals throughout the night, and most return to the roost during the hour before and the hour after sunrise. Diet is mainly the juices of figs *Ficus*, and soft fruits (including, in Comoros, those of *Ceiba*, *Terminalia*, *Vitex*, *Carica papaya* and a variety of other cultivated fruits) and nectar from *Ceiba* and *Erythrina* (Cheke & Dahl 1981, Trehwella *et al.* 2001). Trehwella *et al.* (2001) observed many more individuals in *Ceiba pentandra* trees when they were flowering than subsequently when they were fruiting. A preliminary examination of faecal samples suggested that there is little overlap in the fruits eaten by *P. s. comorensis* and *P. livingstonii* (Trehwella *et al.* 2001). On Mafia I., food plants include *Mangifera* (mango), *Musa* (banana), *Syzygium* (Java plum) and *Terminalia* (Tropical Almond) (Clark 1994 in Trehwella *et al.* 2001). An important cross-pollinator.

Social and Reproductive Behaviour Roosts in colonies (camps) of ca. 20 to more than 2000. Camps are often noisy during the day: individuals fly or clamber from perch to perch, often disturbing their neighbours and starting quarrels. Within each camp, there are different sorts of social groups: pairs of adults, harems comprised of one ♂ with several ♀♀, maternity associations of ♀♀ with young, and groups of subadults. Communication is vocal, visual, olfactory and tactile. Courtship behaviour includes a croaking cry and clapping and rattling of the wings, and it occurs within harems (Cheke & Dahl 1981).

Reproduction and Population Structure Litter-size: one. Reproductive chronology on Mafia I. not known. On Mafia I. one female with large nipples and one placental scar in right uterine horn was found dead in early Aug, and a subadult in late Jul (Kock & Stanley 2009). In the Comoros, the chronology is restricted seasonal monoestry with copulation during the transition between the wet and dry seasons in Apr–Jun (Cheke & Dahl 1981, Trehwella *et al.* 1995). Very small young, still clinging to their mothers, were observed in Jan (Trehwella *et al.* 1995), but the age of these young, and the timing of parturition, is uncertain.

Predators, Parasites and Diseases Humans are probably the main predators.

Conservation IUCN Category: Least Concern (as *P. seychellensis* including *P. s. comorensis*: assessed mainly from extralimital data).

Population trend is stable for nominate subspecies in Seychelles: no data for *P. s. comorensis*. Flying-foxes are particularly prone to electrocution on electricity wires (e.g. Verschuren 1985), and cyclones and severe storms probably reduce their population numbers.

Pteropus voeltzkowi PEMBA FLYING-FOX

Fr. Grande rousette de Pemba; Ger. Pemba-Flugfuchs

Pteropus voeltzkowi Matschie, 1909. Sitzb. Ges. Naturf. Fr. Berlin, p. 486. Fufuni, Pemba I., Tanzania.

Taxonomy Species-group: *niger* – with *P. rufus* (Madagascar), *P. seychellensis* (Seychelles, Comoros and Mafia I. [Tanzania]), *P. aldabrensis* (Aldabra Atoll) and *P. niger* (Reunion and Mauritius) (Koopman 1994). Synonyms: none. *Pteropus voeltzkowi* shows strong morphological similarities to *P. seychellensis* but differs from *P. seychellensis* and other Indian Ocean *Pteropus* in the red colour of its mantle and, for this reason, has retained specific status (Bergmans 1990). Chromosome number: not known.

Description Very large, blackish-brown fruit bat with conspicuous bright rusty-red or rusty-orange mantle; fox-like head without dark face-mask; no ear-patches; no white face-markings; no epaulettes; found only on Pemba I. Sexes similar in colour; ♂♂ on average larger than ♀♀. Pelage dense; mid-dorsal hairs ca. 15 mm. Dorsal pelage: crown dark brown or rusty-brown, with some grey hairs; nape with longer, coarser, rusty-red or rusty-orange pelage forming the 'red' mantle; back and rump black, blackish-brown or dark reddish-brown with some pale grey or rusty-brown hairs. Dorsal hairs rusty-red or blackish-brown. Ventral pelage: chin and throat dark brown merging into dark golden-brown on chest and golden-brown on belly and flanks. In some individuals, the ventral pelage is more uniformly rusty-brown or dark brown becoming paler on the flanks. Muzzle long, tapering, giving head a fox-like appearance; face uniformly rusty-brown (Figure 52b). Ears pointed, naked, very dark brown. Wing-membranes very dark brown (not grey as in Kingdon 1997); attaching to second toe. No tail.

Skull (Figure 52c, d and e) long and robust for an African fruit bat. Rostrum of medium relative length. Dental formula $2^{132}/_{2133} = 34$.

Geographic Variation None.

Similar Species Two other species of large African fruit bats have no basal ear-patches; no white markings on head; FA: >108 mm:

Pteropus seychellensis comorensis. Mantle golden or rusty-yellow ('yellow'); dark face-mask present. Mafia I. only.

Eidolon helvum. Dorsal pelage usually pale and yellowish; no mantle. Smaller (FA: 105–135 mm). Mainland Africa and islands including Pemba I. and Mafia I.

Distribution Endemic to Pemba I. (Tanzania) and its associated islets. Has not been recorded on Zanzibar I., Mafia I., or on the African mainland.

Habitat *Pteropus voeltzkowi* is a small-island specialist. Pemba I. (ca. 984 km²) lies ca. 40 km from the mainland and ca. 40 km from Zanzibar I. Terrain undulating; west side with ridges and steep valleys that are often forested, east side flatter and more arid. Formerly, primary evergreen forest must have been widespread, with evergreen bush in less favourable areas, and mangrove swamps around coast. The primary forest is now reduced to remnants, including two forest reserves and traditional graveyards. Secondary forest is regenerating in extensive abandoned clove plantations. No rivers, many pools (Moreau & Pakenham 1940, Entwistle & Corp 1997a).

Abundance Total world population (June 1995) estimated to be 4600–5500 individuals (Entwistle & Corp 1997a). Nineteen

Pteropus voeltzkowi

occupied camps were located: ten contained 94% of the population. On the basis of a week-long survey in 1989, Seehausen (1991a) suggested that the species was almost extinct; however, the five areas he surveyed did not include the areas where *P. voeltzkowi* was found in 1995.

Adaptations Very little is known, but *Pteropus voeltzkowi* resembles other flying-foxes and its adaptations are likely to be typical of the genus *Pteropus*. By day, hangs in the canopies of leafy trees. Camps are found in primary and secondary forests, mangroves and occasionally in isolated trees. Of the 19 camps located in 1995, 12 were on western side of Pemba. In hilly areas, camps were located on the ridge tops. As in other island-dwelling species of *Pteropus*, many individuals roost on the offshore islets and fly to Pemba for foraging; Pakenham (1984) observed 'hundreds' flying from the islets at dusk. In 1995, one camp was found in a village: the others were 100 m to 5 km away from villages. Many camps are traditional but the extent to which they are occupied may vary seasonally.

Foraging and Food Feeds on fruits, leaves and flowers. Foraging begins when individuals fly from their camps at dusk. Fruits are chewed and crushed against the palatal ridges, pulp and juice is swallowed, fibre and seeds are spat out as pellets. *Pteropus voeltzkowi* feeds on many species of indigenous trees (O. Seehausen in Mickleburgh *et al.* 1992), but shows a preference now for human-introduced species such as mango, breadfruit, jackfruit and papaya. Based on the analysis of 573 faecal pellets collected from 11 camps in Jun and Jul, the diet (expressed as the percentage of pellets containing each different food) was 57% mango, 18% breadfruit, 8% leaves, 5% figs, 7% other fruits and 5% flowers and pollen (Entwistle & Corp 1997b). However, individuals from different camps have different diets, depending on what is available in their foraging areas (e.g. Camp A: leaves 50%, mango 30%, other fruits 15%, flowers 5%. Camp B: figs 70%, breadfruit 20%, leaves 10%). Leaf-eating (which also occurs in *Eidolon helvum*, *Epomophorus wahlbergi* and some other fruit-eating bats) may be a means of obtaining important proteins and minerals that are not obtainable from fruits (Kunz & Diaz 1995). *Pteropus voeltzkowi* probably plays a part in the pollination of some trees (e.g. Kapok *Ceiba pentandra*), and in the transport of seeds from the parent trees to other locations.

Social and Reproductive Behaviour Very little known. Roosts in large to very large groups of mixed sexes and ages.

Reproduction and Population Structure Litter-size and reproductive chronology not known, the available information is inconclusive. Seehausen (1990 in Mickleburgh *et al.* 1992) recorded births 'between the rains' (Jun–Aug). However, Entwistle & Corp

(1997a) did not find evidence of births in Jun and Jul in 1995. 'Young' were recorded in Oct (Seehausen 1991b in Entwistle & Corp 1997a) and are 'first seen' in Aug and Sep (Pemba villagers, in Entwistle & Corp 1997a). There appear to be no reliable data for other times of the year, and therefore it should not be concluded that these observations indicate monoestry.

Predators, Parasites and Diseases Hunted for food by humans (Mickleburgh *et al.* 1992). Voeltzkow (in Pakenham 1984) reported the ectoparasitic bat-fly *Cyclopodia greeffi* (Diptera: Nycteribiidae) to be very numerous. No other ectoparasites recorded (Anciaux de Faveaux 1984).

Conservation IUCN Category: Vulnerable.

Major threats: (apart from extremely restricted distribution and small population size) deforestation, hunting (Seehausen 1990, Mickleburgh *et al.* 1992) and accidental mortality. The increasing human population and pressure on land for agriculture has reduced the areas of the forest that are essential for foraging and roosting. On the other hand, fruit trees planted by humans provide an important source of food. Population trend: stable.

GENUS *Rousettus**Rousettus*

Rousettus Gray, 1821. London Med. Repos. 15: 299. Type species: *Pteropus aegyptiacus* E. Geoffroy, 1810.

Rousettus is a polytypic genus with, according to Simmons (2005), eight species of which two occur in Africa, one on Madagascar, one on the Comoros Is., one from Sri Lanka and Pakistan to S China and Indonesia, and the others in South-East Asia. Diagnostic characters of African species: no white basal ear-patches; no white markings on face; FA: 82–106 mm; no ruff of stiff hairs around the neck; toes not partly webbed; five upper and six lower cheekteeth; M^2 not greatly reduced (Table 11, p. 228). Roosts in caves; some, if not all, species orientate using echolocation as well as vision. Selected characters of African *Rousettus* are illustrated in Figure 53.

Rousettus was placed in the *Rousettus* section of Andersen (1912a), and in the subfamily Rousettinae (tribe Rousettini) by Bergmans (1997). *Rousettus* is considered to contain two or three subgenera by some authors – *Lissonycteris* (Africa), *Stenonycteris* (Africa and Madagascar) and *Boneia* (Indonesia). *Lissonycteris* is now considered a distinct genus, or possibly a synonym or subgenus of *Myonycteris*, and is no longer placed in the subfamily Rousettinae (see genus profile). The status of *Stenonycteris* is controversial. Lawrence & Novick (1963) used differences in behaviour and locomotion (amongst others) to support generic status for *Lissonycteris*, and Kingdon (1974) likewise

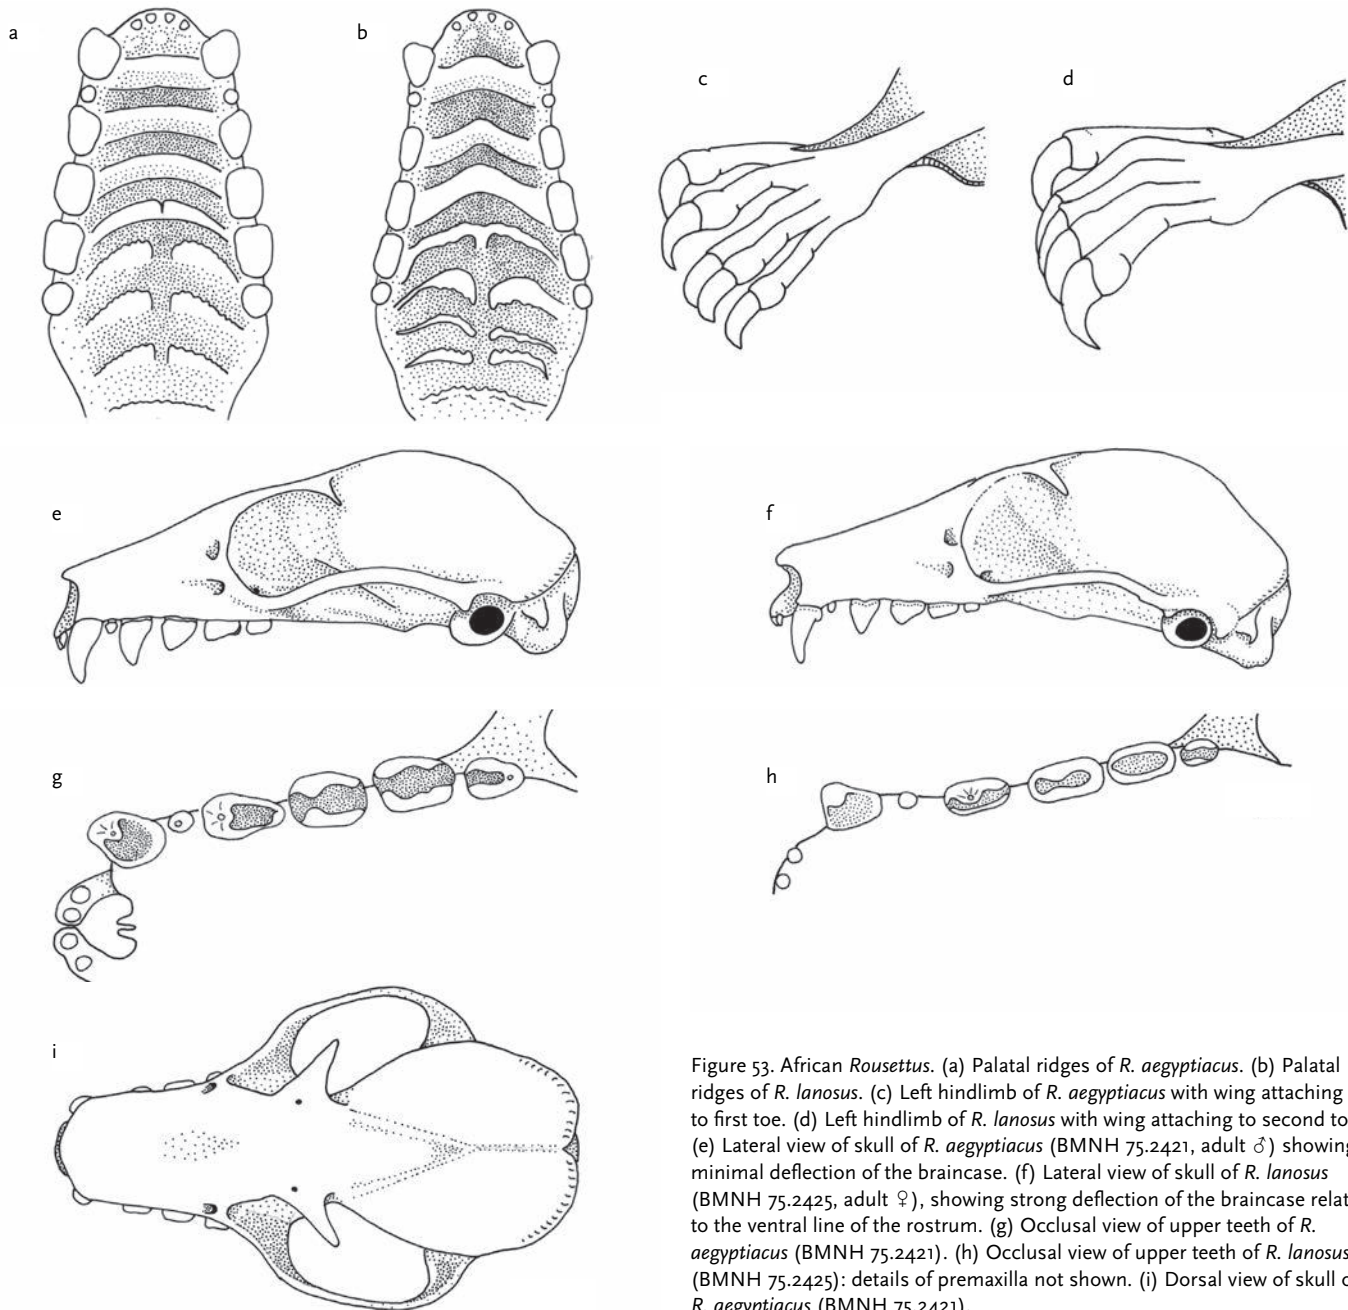

Figure 53. African *Rousettus*. (a) Palatal ridges of *R. aegyptiacus*. (b) Palatal ridges of *R. lanosus*. (c) Left hindlimb of *R. aegyptiacus* with wing attaching to first toe. (d) Left hindlimb of *R. lanosus* with wing attaching to second toe. (e) Lateral view of skull of *R. aegyptiacus* (BMNH 75.2421, adult ♂) showing minimal deflection of the braincase. (f) Lateral view of skull of *R. lanosus* (BMNH 75.2425, adult ♀), showing strong deflection of the braincase relative to the ventral line of the rostrum. (g) Occlusal view of upper teeth of *R. aegyptiacus* (BMNH 75.2421). (h) Occlusal view of upper teeth of *R. lanosus* (BMNH 75.2425); details of premaxilla not shown. (i) Dorsal view of skull of *R. aegyptiacus* (BMNH 75.2421).

Rousettus lanosus.

used differences in behaviour and locomotion between *Rousettus* and *Stenonycteris*, and some craniodental characters, to indicate generic status for *Stenonycteris*. In contrast, Bergmans (1977a, 1994) considers *lanosus* to be a species of *Rousettus*, and does not recognize *Stenonycteris* either as a genus or a subgenus, and he considers *Rousettus madagascariensis* from Madagascar to be intermediate between typical *Rousettus* and *Stenonycteris* in all morphological characters except the narrowness of its cheekteeth, which places it closer to *Stenonycteris*. Cladistic analyses based on molecular genetics are also controversial. According to Álvarez *et al.* (1999) and Juste *et al.* (1999), *R. (Stenonycteris) lanosus* appears more closely related to the myonycterine

clade than to *Rousettus (sensu stricto)*. In contrast, Giannini & Simmons (2003) found that '*Stenonycteris lanosus*' clustered with *Rousettus (sensu stricto)* and *Eonycteris spelaea* (both in the tribe Rousettini of Bergmans 1997) and not with the myonycterine clade. Their analysis also suggests that *lanosus* is more closely related to Indomalayan species of *Rousettus* than to the African *R. aegyptiacus*. *Rousettus aegyptiacus* and other *Rousettus* spp. echolocate, and *R. (S.) lanosus* probably echolocates. If *Stenonycteris* and *Rousettus* are sister taxa, echolocation by tongue-clicks has evolved only once in fruit bats (Giannini & Simmons 2003). Alternatively, if *Stenonycteris* belongs to the myonycterine clade (an endemic African clade) echolocation may have evolved twice (Giannini & Simmons 2003). Pending further information, following Simmons (2005), *Stenonycteris* is presented here as a subgenus of *Rousettus* and it is considered to contain two species, *R. (S.) lanosus* in Africa, and *R. (S.) madagascariensis* in Madagascar.

The species of *Rousettus* in Africa are:

- R. aegyptiacus*. Dorsal pelage sleek and shorter (underfur 6–7 mm, longest hairs ca. 12 mm); antitragal lobe of ear distinct; wing attached to first toe (Figure 53c) or between first and second toes; tibiae dorsally practically naked; skull not delicate; braincase only slightly deflected (Figure 53e); cheekteeth comparatively broad. Widespread and not restricted to mountainous areas.
- R. lanosus*. Dorsal pelage shaggy and longer (underfur 7–8 mm, longest hairs 16–18 mm); antitragal lobe of ear indistinct; wing attached to second toe (Figure 53d) or occasionally between first and second toes; tibiae dorsally well furred; skull delicate; braincase strongly deflected (Figure 53f); cheekteeth narrow. Mountainous areas of eastern Africa.

Meredith Happold

Rousettus aegyptiacus EGYPTIAN ROUSETTE

Fr. Rousette d'Egypte; Ger. Ägyptischer Höhlenflughund (Nilflughund)

Rousettus aegyptiacus (E. Geoffroy, 1810). Ann. Mus. Natn. Hist. Nat. Paris 15: 96. Giza, Egypt.

Taxonomy Originally *Pteropus egyptiacus*. The specific name was corrected to *aegyptiacus* by its author in 1818. This emendation was not accepted by Corbet & Hill (1992) and Bergmans (1994) but is considered justified by Kock (2001a): *aegyptiacus* is the name most often used and it is retained here (following Kock 2001a) and also in the interests of stability. Synonyms: *arabicus*, *egyptiacus*, *geoffroyi*, *hottentotus*, *leachii*, *occidentalis*, *princeps*, *sjostedti*, *thomensis*, *tomensis*, *unicolor*. Subspecies in Africa: four. Chromosome number (*R. a. leachii*, W Uganda): $2n = 36$; $aFN = 68$ (Dulić & Mutere 1973a).

Description Small to medium-sized, dark brown to greyish-brown fruit bat with no white markings; no mantle; no epaulettes; no ruff of coarse hairs; no webbing between toes; pelage moderately long and fairly sleek; wing-membranes usually attaching to first toe. Sexes similar in colour; ♂♂ on average slightly larger than ♀♀. Pelage soft, fairly sleek; extending dorsally and ventrally along each upper arm and ca. half-way along each forearm; mid-dorsal length of underfur hairs 6–7 mm interspersed with hairs up to 4 mm longer. Dorsal pelage dark sepia brown to greyish-brown (pale brown in

Egypt); paler and sparser on neck; hairs on back unicoloured, hairs on neck pale with darker tip. Ventral pelage slightly to considerably paler. Males with stiffer, paler hairs around neck and throat, but without a conspicuous coarse ruff (cf. *Lissonycteris*, *Myonycteris*). Head without markings; muzzle long; lips and cheeks not very expansible. Ears naked, brown, tip rounded; antitragus distinct although weakly developed. Palate usually with four undivided ridges, three divided ridges and one very thin ridge at posterior end of palate (Figure 53a), but the ridge pattern is variable (for details see Bergmans 1994). Wings blackish-brown, wing-membranes attaching to first toe (Figure 53c) or occasionally between the first and second toes. Dorsal side of tibia practically naked (cf. *R. lanosus*). Tail short, protruding up to 17 mm beyond interfemoral membrane.

Skull, on average, medium-sized for an African fruit bat and moderately robust. Zygomatic arches not extremely slender (cf. *R. lanosus*). Rostrum of medium relative length. Premaxillae not fused anteriorly (cf. *Lissonycteris*). Braincase minimally deflected; upper alveolar line straight (Figure 53e). Upper cheekteeth comparatively wide in occlusal view (Figure 53g), breadth of large premolars and

molars clearly greater than half their lengths; cf. *R. lanosus*); M^2 not greatly reduced (cf. *Myonycteris*). Dental formula $^{2132}/_{2133} = 34$.

Geographic Variation Six subspecies are recognized by Juste & Ibáñez (1993a) and Bergmans (1994), of which four occur partly or only in mainland Africa:

Rousettus a. aegyptiacus: Nile Valley of Egypt (and extraliminally northwards to Cyprus and extreme S Turkey, and eastwards to W Arabia).

R. a. arabicus: possibly Djibouti (and extraliminally S Arabia and eastwards to Pakistan).

R. a. unicolor: Senegal to Cameroon, Bioko I. and southwards to Angola.

R. a. leachii: NE DR Congo to Ethiopia and southwards to South Africa; also Pemba I., Zanzibar I. and Mafia I.

Similar Species Four other African mainland species of fruit bats are small to medium-sized (FA: 56–107 mm) with no basal ear-patches and no other white or pale markings on the head:

Rousettus lanosus. Dorsal pelage longer, shaggy. Antitragus indistinct. Wing-membranes attaching to second toe (occasionally between first and second toes); tibiae dorsally well furred. Skull delicate; braincase strongly deflected; cheekteeth narrow.

Lissonycteris angolensis. Usually smaller (FA: 68–90 mm). Dorsal pelage fairly long; ruff of coarse hairs in adult ♂♂. Toes partly webbed. Upper alveolar line with weak angle between 3rd and 4th premolars. Does not orientate acoustically.

Myonycteris spp. Smaller (FA: 56–75 mm). Adult ♂♂ with ruff of coarse hairs.

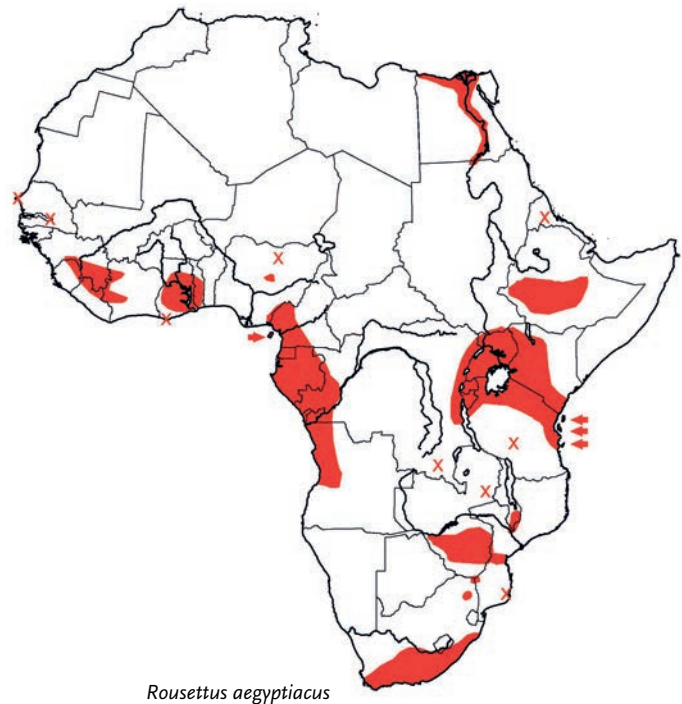

Distribution In Africa, the distribution is disjunct (see Geographic Variation) and restricted to areas with fruiting trees and caves (except in Nile Valley where man-made day-roosts are used), but there are records in all biotic zones and mosaics except the Mediterranean Coastal BZ and the Sahel Savanna BZ. Map based on Bergmans (1994). Not recorded from Somalia (*contra* Kingdon 1997) nor as widely elsewhere as his map indicates. Extraliminally: Cyprus, Turkey, Middle East, Arabian Peninsula, Pakistan, NW India. Also São Tomé I. and Príncipe I. in Gulf of Guinea.

Habitat South of the Sahara, found in most habitats where caves and fruiting trees are present, from 0 to 2500 m. In Egypt, *R. a. aegyptiacus* inhabits cultivated areas in the Nile Valley and Nile Delta and some oases, and it roosts in man-made cave-like day-roosts where caves are absent.

Abundance Common; sometimes very abundant near large caves.

Adaptations This species is particularly well studied, e.g. Möhres & Kulzer (1956), Kulzer (1958, 1963, 1969a, b, 1979), Novick (1958c), Noll (1979a), Laburn & Mitchell (1975), Jacobsen & Du Plessis (1976), Herzig-Straschil & Robinson (1978), Mutere (1968) and Korine *et al.* (1994). For review and more references, see Kwiecinski & Griffiths (1999).

Aspect ratio very low; wing-loading very high to exceptionally high; wing tips short and rounded. Flight-speed slow, reaches 4.4 m/sec; agile at slow speeds, manoeuvrability poor. Sometimes glides when

travelling from higher to lower localities; glide speeds 5.3–11 m/sec. Can hover briefly and take off from the ground. Physiological adaptations associated with the high demand for oxygen during flight include a relatively large heart, high haemoglobin concentration and very high carrying capacity for blood oxygen (Jürgens *et al.* 1981). Locomotion on ground is slow and clumsy, but climbing is efficient (Lawrence & Novick 1963). Frequently hangs from branches or fruits in a sloth-like position with one foot and one thumb on each side of the branch, and frequently moves along underside of branches in this position, using all four limbs (cf. *Lissonycteris angolensis*).

By day, roosts mainly in large humid caves and lava tunnels where temperatures are stable, sometimes choosing dimly lit areas and sometimes choosing areas of total darkness. Hangs in dense clusters, preferring to pack into holes and crevices in the roof, but will hang from ceilings if necessary. In Egypt, it roosts in cave-like buildings including temples, tombs and mosques. Sometimes shares day-roosts with several species of microbats, each species occupying its own area. Mean daily temperatures inside day-roosts sometimes reach 28 °C during the hottest months in Egypt, but are usually lower. However, the thermoneutral zone for *R. aegyptiacus* is narrow and the lower critical temperature (31 °C) is invariably higher than the day-roost temperature; consequently this species must live in colonies and individuals must huddle together to stay within the thermoneutral zone. They do not become torpid and do not hibernate. They warm themselves by huddling, shivering, breathing more rapidly and increasing metabolic heat production (including by metabolizing brown fat) but they cannot survive cold conditions for very long. To cool themselves, normally hydrated individuals move apart, pant, salivate copiously, lick most of the body, dilate the blood-vessels of the wings (but do not fan the wings) and lower the testes.

Rousettus aegyptiacus, and at least two other species of *Rousettus*, echolocates in dark caves and sometimes while flying outside. The echolocation calls always occur in groups of two clicks; they are made with the tongue and emitted through the mouth. The clicks have broad

bandwidths with frequencies of 7–70 kHz; parts of the calls are audible to humans as clicks. Frequencies around 10–12 kHz and 20 kHz contain the most energy, and the hearing curve is finely tuned at ca. 10 kHz with a second peak at 20 kHz. The cochlea is not specialized as in microbats (Hinchcliffe & Pye 1968). The pinnae are highly mobile and are most sensitive to click stimuli in front of the bat when they are directed forwards, and least sensitive when directed backwards; during flight, the ears flicker to and fro and the clicks are emitted when the ears are moving from their least sensitive to their most sensitive position (Holland & Walters 2005). The eyes are large and (as in other fruit bats) are specially adapted for night vision. The sense of smell is highly developed. The follicles of the stiff hairs around the neck and throat are associated with non-specialized sebaceous glands, more active in ♂♂ than ♀♀, suggesting that scent from these hairs provides behavioural cues (Mainoya & Howell 1979). The mean daily total intake of water (from the diet) is 71.7 ml; the kidney has a thin medulla and extremely short papilla, enabling production of dilute urine (113–1800 mOsmol/kg under varying dietary regimes) (Kulzer 1979, Arad & Korine 1993).

Foraging and Food Feeds on fruits, nectar and probably pollen. Sometimes commutes 10–24 km between day-roost and foraging ground, and consequently sometimes arrives much later than competing species that roost in trees nearby (Thomas & Fenton 1978). Fruits are carried to feeding perches. Hard-skinned fruits are peeled before the pulp is chewed and mashed against the palate. Up to 25% of gathered fruit is discarded, often because of attempted pilfering. In South Africa, alimantal migration (seasonal search for food) is implied by fluctuations in colony sizes (Lombard 1961), and marked bats have been recaptured at day-roosts 32–500 km apart. However, these movements might be nomadic rather than migratory. In contrast, in Uganda where food is available year-round, caves shelter thousands of individuals throughout the year. *Rousettus aegyptiacus* eats ripe fruits of many native trees and shrubs and also ripe cultivated fruits. Considered a pest in some areas although damage to orchards is often exaggerated. Takes nectar and probably pollen from flowers including those of *Bombax*, *Kigelia*, *Adansonia*, *Eriobotrya* and *Musa*, and pollinates at least some of these species (Kock 1972). Sometimes chews leaves. In captivity, the mean \pm S.D. nightly consumption of food was 120.3 ± 23.2 g; the mean consumption per unit body weight was $0.94 \text{ g/g}^{\text{bwt}}$ ($n = 7$); the mean through-put time was 20 ± 1 min (Wolton *et al.* 1982), more than twice as fast as in *Lissonycteris angolensis*.

Social and Reproductive Behaviour Roosts in groups (colonies) of ca. 50–4000 or more individuals of both sexes. A cave may contain several clusters of huddled bats, but the composition and stability of clusters is apparently not known. Fluctuations in adult sex ratios of colonies are recorded in South Africa and Israel; ♀♀ usually outnumber ♂♂ by as much as 3 : 1, suggesting polygamy (Jacobsen & Du Plessis 1976). During pregnancy and lactation, two caves in South Africa and one in Israel contained 25–33% adult ♂♂, suggesting that ♀♀ do not form maternity colonies in separate caves. However, Lombard (1961) noted that, in captivity, ♂♂ tended to form groups, ignoring the ♀♀ and juveniles, and therefore the possibility that occupants of a single cave segregate into maternity clusters and bachelor clusters needs investigation. There appears to be no other evidence of sexual separation (*contra* Kwiecinski & Griffiths 1999), nor any records of day-roosts occupied exclusively by ♀♀ with young.

Colonies remain active and noisy throughout much of the day. There is often competition for the darkest sites, and bats will move from lighter to darker positions if light levels increase during the day. Competition for particular positions within clusters is evident from aggressive interactions including screaming, striking out with the forearms, hooking an opponent and biting. Individuals are recognized primarily by their scent, and olfactory cues probably influence many social interactions. A wide range of vocalizations are made, many probably associated with communication.

Copulation occurs at the roost. During birth, the ♀ remains quiescent in the normal resting posture. Eventually the head of the baby appears and then the baby slowly squirms its way out of the vagina, thus participating actively in its own delivery. The wings are freed first and then the legs. Still attached to the umbilical cord, it climbs down over the mother's pelage, searches for a nipple and attaches firmly with its milk-teeth. Only then is the placenta delivered and eaten (Kulzer 1966, 1969b). The neonate remains attached to its mother for ca. 16 days, and is carried when she forages. Later, juveniles are left in the day-roost, in clusters of other juveniles.

Reproduction and Population Structure Litter-size: usually one, occasionally two. Reproductive chronology varies geographically – both monoestry and polyoestry and both seasonal and aseasonal chronologies are known. In Egypt, copulation and births occur in all months, gestation 105–107 days; not known if this population is polyoestrous. At 00° 22'S (Kasokero, Uganda), the chronology is seasonal bimodal polyoestry without postpartum oestrus, with gestation four months and births just before peaks in rainfall (Mar and Sep), and an interval of two months between parturition and the next conception (Mutere 1968). At 22° 25'S (Pafuri, Kruger N. P., South Africa), the chronology is restricted seasonal monoestry with copulation in winter (Jul–Aug), births in summer (Nov–Dec) with 95% pregnancy rate, and lactation for ca. two months (Penzhorn & Rautenbach 1988). In contrast, at ca. 24° S in the former Transvaal, South Africa, there is extended seasonal monoestry with copulation in Jun–mid-Sep, births in late Oct–Dec with a peak in Nov–Dec (Jacobsen & Du Plessis 1976). Further south at ca. 34° S (Tsitsikama Coastal N. P., Eastern Cape Province), the chronology for most ♀♀ is extended seasonal monoestry with births from Oct–Jun with a peak in Dec (Herzig-Straschil & Robinson 1978), but the possibility that births in Jun are the result of polyoestry in a few ♀♀ needs investigation. Data from other African localities are inconclusive.

Neonates have thin downy fur on the head and back; eyes are closed; ear pinnae pressed against head; birth-weight 18–25 g. Ears become erect and eyes open ca. day 10. By day 36, wing-span is 75% of adult span. Adult-size and weight attained ca. nine months (Kulzer 1979, Noll 1979b). Sex ratio at birth is 1 : 1.

Predators, Parasites and Diseases Predators include Genets *Genetta* spp., Lanner Falcons *Falco biarmicus*, hawks (species not identified) and owls *Bubo bubo* (Kulzer 1969b, Jacobsen & Du Plessis 1976 and Qumsiyeh 1985). In some areas, taken by humans for food, or because of supposed damage to crops. Ectoparasites include bed-bugs *Afrocmex leleupi*, *A. constrictus* (Hemiptera: Cimicidae), another bug *Eothenes intermedius* (Hemiptera: Polyctenidae); fleas *Archaeopsylla erinacei* (Siphonaptera: Pulicidae), *Thaumapsylla breviceps* (Siphonaptera: Ischnopsyllidae); bat-flies *Basilia blainvillii*,

Dipseliopoda biannulata, *D. setosa*, *Eucampsipoda hyrtlai*, *E. africana* (Diptera: Nycteribidae), *Brachytarsina diversa*, *B. alluaudi* and *B. bequaerti* (Diptera: Streblidae) (Anciaux de Faveaux 1984). Viruses isolated from *R. aegyptiacus* include Chikungunya virus, isolated from Ugandan material (Addy *et al.* 1978).

Conservation IUCN Category: Least Concern.

Meredith Happold

Rousettus lanosus LONG-HAIRED ROUSETTE

Fr. Roussette laineuse; Ger. Gebirgs-Höhlenflughund

Rousettus lanosus Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 137. Mubuku Valley, Rwenzori East, Uganda.

Taxonomy Subgenus *Stenonycteris*. The taxonomy of *lanosus* is controversial: analyses based on morphological, molecular and behavioural data have sometimes placed this taxon in *Rousettus* (with no subgenera recognized), sometimes in *R. (Stenonycteris)*, and sometimes *Stenonycteris* is given full generic status (see profile Genus *Rousettus*). Based on a combination of morphological and molecular data, Giannini & Simmons (2003) and Simmons (2005) concluded that *Stenonycteris* is a subgenus of *Rousettus*, and pending resolution of all incongruencies, this view is held here. Synonyms: *kempi*. Subspecies: two of dubious validity. Chromosome number: not known.

Description Small to medium-sized, brown fruit bat with no white markings; no epaulettes; no ruff of coarse hair around the throat; no webbing between the toes; pelage long and shaggy; wing-membranes usually attaching to second toe. Sexes similar. Pelage shaggy, slightly coarse, underfur woolly; dorsal pelage extending along each upper arm and half-way along each forearm, over the interfemoral membrane, and also over the tibiae (cf. *R. aegyptiacus*); mid-dorsal length of underfur hairs 7–8 mm interspersed with hairs of 16–18 mm. Dorsal pelage medium to dark greyish-brown to dark rusty-brown, sometimes with scattered paler hairs; hairs unicoloured. Ventral pelage slightly paler, sometimes with more scattered paler hairs. Adult ♂♂ with longer, slightly stiffer hairs on neck and throat, but no conspicuous ruff of coarse hairs (cf. *Lissonycteris*, *Myonycteris*). Head without markings; muzzle long; lips and cheeks not very expansible. Ears naked, dark brown; antitragal lobe vestigial and indistinct. Palate usually with four undivided ridges, three divided ridges and one very thin ridge at the posterior end of the palate (Figure 53b), but some individuals have four undivided ridges (Bergmans 1994). Eyes blackish. Wing-membranes dark brown, attaching to second toe (Figure 53d) or occasionally between first and second toes. Dorsal surface of tibiae

well furred (cf. *R. aegyptiacus*). Tail protruding up to 16 mm beyond interfemoral membrane.

Skull medium-sized for an African fruit bat but delicate. Zygomatic arches extremely slender (cf. *R. aegyptiacus*). Rostrum of medium relative length. Premaxillae not fused (cf. *Lissonycteris*). Braincase strongly deflected ventrally; upper alveolar line straight (Figure 53f). Upper cheekteeth comparatively narrow in occlusal view (Figure 53h), breadth of large premolars and molars equal to half their lengths or slightly more (cf. *R. aegyptiacus*); posterior upper molar (M²) not greatly reduced (cf. *Myonycteris*). Lower cheekteeth also narrow. Dental formula $2^{132}/_{2133} = 34$.

Geographic Variation Bergmans (1994) preferred not to distinguish subspecies until the distribution and geographic variation are better known, but two subspecies are recognized by some authors including Hayman & Hill (1971), Aggundey & Schlitter (1984) and Koopman (1994):

R. l. lanosus: E DR Congo, Burundi, Rwanda and W Uganda.

R. l. kempi: E Uganda, Tanzania, Kenya, SW Sudan, Ethiopia.

Similar Species Four other African mainland species of fruit bats are small to medium-sized (FA: 56–107 mm) with no basal ear-patches and no other white or pale markings on the head:

Rousettus aegyptiacus. Dorsal pelage shorter, sleek; antitragus distinct; wing usually attaching to first toe (occasionally between first and second toes); tibiae dorsally practically naked. Skull not delicate; braincase only slightly deflected; cheekteeth comparatively broad. *Lissonycteris angolensis*. Usually smaller (FA: 68–90 mm). Ruff of coarse hairs in adult ♂♂; antitragus distinct; toes partly webbed. Upper

alveolar line with weak angle between 3rd and 4th premolars; cheekteeth broad and squarish. Does not orientate acoustically. *Myonycteris* spp. Smaller (FA: 56–75 mm). Adult ♂♂ with ruff of coarse hairs.

Distribution Endemic to Africa. Occurs mainly in the Afromontane–Afroalpine BZ in S Sudan, SW Ethiopia, E DR Congo, Rwanda, Uganda, Kenya, Tanzania and Malawi. Also occurs in Burundi according to Koopman (1994), but this locality has not been traced or mapped. Map based on Bergmans (1994).

Habitat Mostly recorded in, or on the borders of, undifferentiated afromontane vegetation, but also recorded in mosaics of East African evergreen bushland and secondary *Acacia* woodland, and occasionally in drier lowland rainforest, wetter and drier miombo woodland, East African evergreen and semi-evergreen bushland and thicket, and *Acacia–Combretum* deciduous bushland and thicket (Bergmans 1994; terminology from White 1983). Occurs from 500 to 4000 m, but most locality records (72%) are between 1500–2500 m, indicating that this species is mainly, but not strictly, montane (Bergmans 1994).

Abundance Uncertain. Sometimes abundant near caves in suitable habitat (Kingdon 1974), but there are few records.

Adaptations Wing morphology and flight characteristics: no information. By day, roosts in dark, damp caves and mine-adits, sometimes in the twilight zone and sometimes in total darkness (Kingdon 1974). Since the roosts are mostly at high altitudes, these bats are often exposed to sub-zero temperatures at night, and low temperatures in their caves: they are probably obliged to roost in clusters (see below) to conserve heat and a comparison of temperature regulation in this species and in *R. aegyptiacus* would be most interesting. Sometimes shares caves with *R. aegyptiacus* and/or *Lissonycteris angolensis*. When flying in total darkness, *R. lanosus* produces a series of clicks similar, although more ‘musical’, to the echolocation clicks produced by *R. aegyptiacus* (Kingdon 1974). It is probable that *R. lanosus* echolocates, but this is not yet confirmed.

Foraging and Food The fragility of the skull, and comparative weakness of the dentition, suggests that the diet of *R. lanosus* is very soft fruits, nectar and perhaps pollen. In Rwanda, a bat believed to be *R. lanosus* was seen feeding on a flower of *Lobelia gibberosa* at ca. 2900 m (Hutson & Wilson 1992).

Social and Reproductive Behaviour Roosts in groups (colonies) of up to several hundred individuals. Like *R. aegyptiacus*, individuals hang huddled together in clusters. Kingdon (1974) observed that, in one mine-adit, pregnant and lactating ♀♀ with young clustered in the twilight zone while the rest of the colony roosted deeper inside. He suggested that, within single day-roosts, the sexes separate and maternity colonies are established, but this needs confirmation. Sometimes, sexually active ♂♂ were observed in the ‘maternity’ cluster. The number of ♀♀ and young in the ‘maternity’ cluster varied from month to month.

Reproduction and Population Structure Litter-size: one (n = 1). Reproductive chronology uncertain. In W Uganda, Kingdon

Rousettus lanosus

(1974) collected one lactating ♀ with her uterus filled with semen, and he also reported that ‘some of the females that were still nursing were already pregnant again’. This indicates polyoestry in at least some females, but further observations are needed to elucidate the chronology in detail. Not known when young are born.

Predators, Parasites and Diseases Ectoparasites include fleas *Thaumapsylla breviceps*, *T. dina* (Siphonaptera: Ischnopsyllidae); bat-flies *Phthiridium scissum*, *Dipseliopoda setosa* (Diptera: Nycteribiidae), *Brachytarsina bequaerti* (Diptera: Streblidae); and a mite *Macronyssus granulosus* (Acari: Macronyssidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Major threats: loss of habitat and hunting by humans.

GENUS *Scotonycteris*

Tear-drop Fruit Bats

Scotonycteris Matschie, 1894. Sitzb. Ges. Naturf. Fr. Berlin, p. 202. Type species: *Scotonycteris zenkeri* Matschie, 1894.

Scotonycteris is a polytypic genus with two species, endemic to Africa, found mainly in the Rainforest BZ from Guinea and Liberia to E DR Congo. Diagnostic characters: white markings on the nose and behind the eyes and usually a more or less conspicuous white border to the upper lip; one species with inconspicuous or without white basal ear-patches, one species without ear-patches; dorsal hairs tricoloured; adult ♂ without epaulettes; FA: 47–87 mm; postdental bony palate extending posteriorly well beyond the teeth, its lateral margins converging posteriorly; rostrum (viewed laterally) not slightly upturned; canines long to very long; three upper and five lower cheekteeth. The palatal ridges of *Scotonycteris zenkeri* are shown in Figure 54a. The skull of *Scotonycteris zenkeri* (Figure 54b) illustrates the basic characters of the genus, but there are substantial inter-specific differences in size and dentition (see below and Figure 54c, f and g). Similar to *Casinycteris* but see Table 11, p. 228.

Scotonycteris was placed in the epomophorine section of Andersen (1912a). He considered this genus to be closely related to *Casinycteris* and, more distantly, to *Nanonycteris*. Hence Andersen (1912a) grouped

these genera in the ‘*Nanonycteris* branch’. In recent phylogenetic analyses, *Scotonycteris* grouped with *Casinycteris*, and this clade grouped together with an epomophorine clade including *Epomophorus*, *Epomops*, *Hypsignathus*, *Micropteropus* and *Nanonycteris* (Springer *et al.* 1995, Jones *et al.* 2002). Consequently, *Scotonycteris* was placed with *Casinycteris* in the tribe Scotonycterini (subfamily Epomophorinae) by Bergmans (1997). According to the data by Romagnoli & Springer (2000), however, *Scotonycteris* and *Casinycteris* would group as a derived clade together with *Micropteropus* and within the other epomophorine fruit bats. The karyotype of *Scotonycteris ophiodon* is very distinct from other investigated African species of fruit bats, i.e. *Micropteropus*, *Epomops*, *Hypsignathus*, *Megaloglossus*, *Myonycteris*, *Lissonycteris* and *Rousettus* (Haiduk *et al.* 1980, 1981; but note that neither *S. zenkeri* nor *Casinycteris argynnis* was examined in these studies). Novick (1958a) suggested that the peculiar dental features of *S. ophiodon* merit subgeneric recognition.

The two species are:

S. ophiodon. FA: 73–87 mm; GLS: 35.3–42.9 mm; WT: 60–95 g.

S. zenkeri. FA: 47–55 mm; GLS: 24.0–27.4 mm; WT: 16–24 g.

Jakob Fahr

***Scotonycteris ophiodon* POHLE'S FRUIT BAT (SNAKE-TOOTHED FRUIT BAT)**

Fr. Scotonyctère à dents de serpent; Ger. Schlangenzähniger Harlekin-Flughund (Pohles Harlekin-Flughund)

Scotonycteris ophiodon Pohle, 1943. Sitzb. Ges. Naturf. Fr. Berlin 1942: p. 78 [publ. 1943]. Bipindi, Kribi District, Cameroon.

Taxonomy Synonyms: *cansdalei*. Subspecies: none (but see Geographic Variation). Novick (1958a) suggested that the peculiar dental features of *S. ophiodon* merit subgeneric recognition. Chromosome number (Cameroon): $2n = 34$; $aFN = 62$; very distinct from other African pteropodid karyotypes (Haiduk *et al.* 1980, 1981, but these authors did not examine *S. zenkeri* and *Casinycteris argynnis*).

Description Very small to small fruit bat with face-markings (white patch on forehead, white posterior eye-spots, broad white band around lips); no conspicuous basal ear-patches; no epaulettes; snout and finger-joints yellowish; forehead region of skull weakly concave; bony palate extending well beyond last teeth; premolars and molars with distinct cusps; FA: 73–87 mm. Sexes similar in colour, ♀♀ on average with slightly longer forearms. Pelage dense, soft and woolly dorsally; much shorter and sparser ventrally with very short and stiff hairs on chest and belly; mid-dorsal hairs 9–10 mm. Dorsal pelage medium brown to rusty-brown, mottled; hairs tricoloured, whitish to very pale grey with dark brown or blackish base and brown tip. Ventral pelage with chin, throat, breast and central belly white or whitish-grey; flanks medium to dark brown, contrasting with paler areas. No epaulettes or white markings on shoulders. Head brown with three conspicuous white patches (one on forehead between anterior corners of eyes, and one at posterior corner of each eye); skin of upper lip and front of muzzle greenish-yellow; lips bordered by broad band of white hair, conspicuously white except under nostrils; anterior basal ear-patches indistinct or absent. Muzzle broad, fairly short; cheeks of adult ♂♂ strikingly wide and capacious; upper lip moderately expansible, internally fringed with conspicuous papillae. Ears dark brown with yellowish rim (paler near base), naked, oval, somewhat pointed at tip. Eyes large, greenish-brown. Palate usually with six thick, undivided interdental ridges and 10–13 narrow, serrated postdental ridges. Wing-membranes brown with marked yellowish-green reticulation (in subadults, more or less uniformly medium to dark brown); attaching to first toe. Finger-joints of adults yellowish to bright greenish-yellow. Thumb comparatively long. Penis and scrotum of (? sexually active) ♂♂ also bright greenish-yellow. No visible tail.

Skull with braincase rounded; rostrum of medium relative length (33–37% of GLS), not upturned. Profile of forehead region (viewed laterally) weakly concave (cf. *Casinycteris*). Zygomatic width relatively narrow (62–64% of GLS) and zygomatic arches comparatively lightly built with lower margin level with infraorbital foramen (cf. *Casinycteris*). Bony palate extending well beyond last teeth. Canines comparatively long and with well-developed secondary cusps on inner edges. Upper canines strongly backward curved (*ophiodon* means snake-toothed); inner edges markedly serrated (Figure 54f and g) (cf. *S. zenkeri*, *Casinycteris* and all other fruit bats). Premolars and molars (except anterior premolar and posterior molar of lower tooththrow) with two distinct cusps on inner and outer side of each tooth, giving a bifurcated appearance. Dental formula usually $2121/_{2132} = 28$.

Geographic Variation Not yet adequately assessed because sample sizes are too small. Specimens from Liberia, Côte d'Ivoire and Ghana seem to be similar in measurements but specimens from Cameroon are slightly larger. Two ♀♀ from Dimonika, Congo (one subadult) are larger than any specimens from elsewhere (FA: 87, 82 mm, GLS: 42.9, 38.0 mm, GWS: 27.3, 23.1 mm, C–M¹: 15.1, 13.8 mm) (Bergmans 1973, 1979, 1990). A very small, adult ♂ from Goumina, Congo (FA: 68 mm; GLS: 29.6 mm, GWS: 22.0 mm, C–M¹: 10.2 mm) with different palatal ridges and peculiar dental characters was published by Dowsett *et al.* (1991) as *S. ophiodon*. This specimen represents an undescribed species and is not included here (J. Fahr unpubl.).

Similar Species Only two other species of African fruit bats have white markings on the nose, upper lips and near the eyes:

Scotonycteris zenkeri. Much smaller (FA: 47–55 mm). Finger-joints not yellowish.

Casinycteris argynnis. Much smaller (FA: 50–62 mm; GLS: 22.2–28.4 mm). Rostrum upturned; bony palate barely extending beyond last teeth.

Distribution Endemic to Africa. Rainforest BZ (Western and West Central Regions). Known from only 15 localities, in Liberia, Côte d'Ivoire, Ghana, Cameroon and Congo. Known range very small and apparently disjunct (12,600 km² in E Liberia and SW Côte d'Ivoire, 14,700 km² in S Ghana, 7500 km² in Cameroon), and a single locality in Congo. Mt Nimba, ca. 250 km inland, is the locality

Scotonycteris ophiodon

furthest from the coast; absent from the central Congo Basin. The distribution partly resembles the assumed distribution of Pleistocene rainforest refugia. Gaps in the distribution are likely to be real because this species has never been found in some intensely surveyed areas between the regions of distribution, e.g. NE Gabon. Mostly recorded with *S. zenkeri*, except at Dugbe R. near Jaoudi in Liberia. In contrast, *S. zenkeri* is known from many regions from which *S. ophiodon* has not been recorded (e.g. East Central Region of the Rainforest BZ and the lowland forest and foothills along the western slope of the mountains flanking the Albertine Rift).

Habitat One of the few African fruit bats that seems to be restricted to the Rainforest BZ. Within this biotic zone, it has been recorded from lowland rainforest, montane forest and coastal forest vegetation zones. In Côte d'Ivoire, Ghana, Cameroon and Congo, seems to prefer lowland rainforest up to 600 m (Eisentraut 1973a, Bergmans 1990, J. Fahr unpubl.). In Liberia, it has been caught fairly frequently on Mt Nimba up to 1200 m where it seems most abundant in montane forest dominated by *Parinari excelsa* (Wolton *et al.* 1982). However, it is not confined to the immediate vicinity of Mt Nimba but also occurs in the lowland rainforests of SE Liberia and adjacent Côte d'Ivoire. In Congo, recorded from degraded rainforest in an area with low mountains (Bergmans 1973).

Abundance Locally rare to very rare. In Tai N. P., Côte d'Ivoire, comprised 6.5% of the fruit bat catch ($n = 1216$ individuals) and was the fifth most abundant species in a community of eight species of fruit bats (J. Fahr & S. Pettersson unpubl.). At Mt Nimba, Liberia, comprised 1.0% of the fruit bat catch ($n = 979$; Wolton *et al.* 1982) and was the seventh most abundant species in a community of nine species of fruit bats.

Adaptations Probably roosts in vegetation; one individual was found hanging from a forest tree (Hayman 1945). Recapture-rate in Tai N. P. 17.1% ($n = 41$); most recaptures up to half a year later; three recaptured one year later. All (including subadults and young-adults) were recaptured less than 400 m from initial site (most less than 250 m) suggesting that home-ranges are very small (several ha) and site-fidelity is unusually high (J. Fahr unpubl.). Frequency of captures varied throughout night, with three distinct peaks: 19:30–20:30h, 23:30–02:30 h, and 03:30 h to dawn. In captivity, the 1.5 hours before dawn were spent extensively grooming the body (Wolton *et al.* 1982).

Foraging and Food Frugivorous. Eisentraut (1959) caught three individuals in elevated nets and concluded that this bat might forage in the upper forest strata. Data from Tai N. P. partly support this (median capture height 18.4 m, $n = 40$) but also indicate foraging from ground to canopy level (min–max: 1.1–23.6 m) (J. Fahr unpubl.). Captive bats fed more or less continuously from ca. 21:00h to 06:00h, but usually rested for ca. 20 minutes, two or three times per night (Wolton *et al.* 1982). The unique dentition suggests a specialized diet or way of feeding. While most other fruit bats hang vertically (from one foot) and hold fruit in the other foot while eating it, *S. ophiodon* hangs horizontally (with both feet and thumbs gripping a branch), and keeps its food on its chest: pieces are bitten off and slowly masticated until the fibrous parts are spat out as pellets. Diet mostly unknown.

Eisentraut (1959) found *Ficus* seeds in stomach. In Tai N. P., most captured individuals had *Ficus* seeds in faeces and some were caught with entire figs in mist nets. Captive bats at Tai N. P. ate fruits of *Parinari excelsa* (J. Fahr unpubl.), and those at Mt Nimba ate fruits of *Ongokea gore*, bananas, plantains and guavas (Wolton *et al.* 1982). In captivity, the mean \pm S.D. nightly fruit consumption was 49.6 ± 8.5 g ($n = 7$); the dry weight assimilated was 81%; and the mean consumption per unit body weight was lower (0.79 g/g^{bwt}) than in five other species of fruit bats (0.92 – 1.18 g/g^{bwt}) (Wolton *et al.* 1982). The ratio between body length and intestine length is 1 : 5.4 (5.1–5.7), which is typical for (mainly) frugivorous fruit bats (Eisentraut 1959).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Litter-size: one ($n = 6$). Reproductive chronology uncertain. At $05^{\circ}50'N$ (Tai N. P., Côte d'Ivoire), 9 adult ♀♀ were neither pregnant nor lactating in Jan–Feb; 3 of 11 were lactating in Mar, 1 of 5 was pregnant in May, 1 of 4 was pregnant in Aug, 12 of 15 were pregnant in Sep, 1 of 1 was pregnant in Oct, and 2 of 7 were pregnant and one was lactating in Dec; none of the ♀♀ was simultaneously lactating and pregnant; no data for other months (J. Fahr unpubl.). At $07^{\circ}32'N$ (Mt Nimba, Liberia), one ♀ was not palpably pregnant in Jul, 2 of 2 were pregnant in late Aug, 1 of 1 was pregnant in early Sep and 1 of 1 was pregnant (CR: 33 mm) in mid-Nov; no data for other months (Wolton *et al.* 1982). At $04^{\circ}20'N$ (Malende, Cameroon), a pregnant ♀ (CR: 23 mm) was recorded in mid-Dec (Eisentraut 1959). At $05^{\circ}55'N$ (Oda, Ghana), a lactating ♀ was found in Dec (Hayman 1945). These data suggest that in West Africa and Cameroon most ♀♀ are pregnant between Aug–Dec, that most births occur at end of wet season (ca. Nov–Dec), and that most ♀♀ lactate during the dry season (between Dec–Mar). The data are compatible with extended seasonal monoestry, but more data are needed to confirm the chronology. Data from four marked and recaptured ♀♀ is also indicative of monoestry: one was pregnant in two consecutive Septembers and reproductively inactive in the intervening Mar; one was pregnant in two consecutive Septembers and reproductively inactive the following Mar, and one was reproductively inactive in Feb and pregnant the following Aug.

The ratio of ♂♂ to ♀♀ in 73 individuals captured at Tai N. P. was 1 : 1.9. In museum collections, the ratio in 22 specimens was 1 : 1.

Predators, Parasites and Diseases Ectoparasites include a mite *Binuncus* (*Binuncus*) *scotonycteris* (Acari: Myobiidae) (Uchikawa 1986).

Conservation IUCN Category: Near Threatened.

Close to qualifying as Vulnerable because of its small and disjunct area of occupancy (see Distribution), its low abundance and strong dependency on forest habitat. Major threats: agriculture, mining, selective logging and deforestation. Human activities in historic times have reduced the area of forests in West Africa by at least 88.5%. Several of the sites where this species is known to occur, e.g. Mt Nimba, forest sites in Ghana, and Mt Cameroon, are under heavy pressure from mining, logging and encroachment by farmers. Population size unknown, population trend inferred as strongly declining (>50%) due to loss of habitat.

Scotonycteris zenkeri ZENKER'S FRUIT BAT

Fr. Scotonyctère de Zenker; Ger. Zenkers Harlekin-Flughund

Scotonycteris zenkeri Matschie, 1894. Sitzb. Ges. Naturf. Fr. Berlin 1894: p. 202. Yaunde [=Yaoundé], Cameroon.

Taxonomy Synonyms: *bedfordi*, *occidentalis*. Subspecies: three, but limits uncertain (see Geographic Variation). Chromosome number (Gabon): 2n = 32 (Primus *et al.* 2006); as a result of conventional staining, no detailed comparison could be made with the banded karyotype of *S. ophiodon*, which is very distinct from other African fruit bats.

Description Very small fruit bat with face-markings (white patch on forehead, white posterior eye-spots, partly white or pale lips); no conspicuous basal ear-patches; no epaulettes; snout and finger-joints not yellowish; forehead region of skull almost straight; bony palate extending well beyond last teeth; cusps of premolars and molars relatively weak; FA: 47–55 mm. Sexes similar in colour; ♀♀ on average with slightly longer forearms. Pelage dense, soft and woolly dorsally; shorter and sparser ventrally with stiff hairs on chest and belly; mid-dorsal hairs 9–10 mm. Dorsal pelage medium sepia brown to rusty-brown, mottled; hairs tricoloured, white or whitish with dark brown at base and sepia brown to rusty-brown at tip. Ventral pelage with lower breast and central belly whitish to pale grey, flanks medium to dark brown or greyish-brown, contrasting with the paler areas. No epaulettes or white markings on shoulders. Head with three conspicuous white patches, one on forehead (between anterior corners of eyes) and one at posterior corner of each eye; anterior basal ear-patches indistinct or absent; no posterior basal ear-patches; lips usually bordered by a narrow and indistinct band of white or pale hairs around each corner. Muzzle short, slender; lips only moderately expansible. Ears dark brown (paler near base), naked; oval with broadly rounded tip. Eyes large, dark brown. Palate with four thick and smooth ridges (the first three undivided, the fourth sometimes medially divided) and 6–9 very thin, serrated and irregular ridges (Figure 54a). Wing-membranes dark greenish-brown or brown, reticulated; attaching to first toe; finger-joints not yellowish (cf. *S. ophiodon*). No visible tail.

Skull short and delicate for an African fruit bat. Braincase rounded; rostrum relatively short (30.4–34.6% of GLS), not upturned. Profile of forehead region (viewed laterally) almost straight (cf. *Casinonycteris*). Zygomatic width relatively narrow (62–69% of GLS) and zygomatic arches comparatively lightly built and with lower

margin level with infraorbital foramen (cf. *Casinonycteris*). Bony palate extending well beyond last teeth. Upper incisors comparatively short. Upper canines only moderately long, with faint inner groove, not conspicuously curved, and without secondary cusps or serrated inner edges (cf. *S. ophiodon*). Premolars and molars rounded to slightly oval in transverse section, with moderate outer cusps but only faint inner cusps (cf. *S. ophiodon*, *Casinonycteris argyannis*). Dental formula usually $^{2121}_{2132} = 28$ (variations known).

Geographic Variation Three subspecies are tentatively recognized here with the following distributions:

S. z. zenkeri: E Nigeria, Cameroon, Gabon and mainland Equatorial Guinea.

S. z. bedfordi: Bioko I.

S. z. occidentalis: Liberia, Guinea, Côte d'Ivoire, Ghana.

Andersen (1912a), Eisentraut (1959) and Kuhn (1961) questioned subspecific differences. However, Bergmans (1990) demonstrated morphological differentiation between five disjunct populations in (1) Liberia, Côte d'Ivoire, Ghana, (2) W Nigeria, (3) Cameroon, mainland Equatorial Guinea and probably E Nigeria, (4) Bioko I. and (5) E DR Congo, which differ in size and/or cranial and dental morphology. This is not adequately reflected in the above subspecific classification. Furthermore, there are isolated records from Congo and Central African Republic and it is not yet clear if these should be assigned to one or more of the above populations or if they represent additional independent and disjunct enclaves. Apart from cranial and dental differences, the population from W Nigeria seems to average largest in measurements while that from Bioko I. is smallest (Bergmans 1990).

Similar Species Only two other species of African fruit bats have white markings on the nose, upper lips and/or near the eyes:

Casinonycteris argyannis. Forearm often longer (50–62 mm). Finger-joints pale yellowish. Forehead region of skull strongly concave; rostrum upturned; bony palate barely extending beyond last teeth.

Scotonycteris ophiodon. Much larger (FA: 73–87 mm). Finger-joints yellowish.

Distribution Endemic to Africa. Mainly found in the Rainforest BZ (Western, West Central and East Central Regions) and marginally in the Afromontane–Afroalpine BZ. Recorded, disjunctly, from Guinea, Liberia, Côte d'Ivoire, Ghana, Nigeria, Cameroon, Equatorial Guinea (including Bioko I.), Gabon, Central African Republic, Congo and DR Congo. Not yet recorded from Dahomey Gap. A gap between records from W Nigeria and E Nigeria mentioned by Bergmans (1990) has been partly bridged by a record from Orashi, Niger Delta (Angelici *et al.* 2000). The records from Central African Republic, E DR Congo and Congo appear isolated. This species has been found at almost all localities where *S. ophiodon* occurs but is much more widely distributed than the latter.

Habitat Recorded in lowland rainforest, coastal forest, montane forest, swamp forest, mangroves and marginally in forest–savanna mosaic vegetation zones. Recorded up to 1000 m on Mt Nimba (Verschuren 1976) and up to 1100 m on Mt Kupé and Rumpi Hills, Cameroon (Eisentraut 1973a). However, seems to prefer lowland rainforests and usually is not found higher than 500–800 m (Eisentraut 1973a, Coe 1975, Wolton *et al.* 1982, Fedden & Macleod 1986). On Bioko I., only found below 400 m (Juste & Perez del Val 1995). Occurs in both pristine and disturbed rainforest and has been mist-netted frequently near forest fringes, in gardens and forest gaps but never in extensively cleared areas or far from closed forest (Eisentraut 1959, Brosset 1966, Jeffrey 1975, Happold & Happold 1978, Wolton *et al.* 1982, J. Fahr unpubl.). On Bioko I., mist-netted significantly more often in cultivated clearings than in lowland rainforest (Juste & Perez del Val 1995). The habitats in Congo are described as degraded rainforest in an area with low mountains (Bergmans 1973) and heavily disturbed low-altitude forest dominated in the understorey by *Haumania liebrechtsiana* (Marantaceae) (Dowsett *et al.* 1991).

Abundance Locally rare to very rare. In Tãï N. P., comprised 3.6% of fruit bat catch ($n = 1216$ individuals); sixth most abundant species in community of eight species of fruit bats (J. Fahr & S. Pettersson unpubl.). At Mt Nimba, comprised 2.7% of the fruit bat catch ($n = 979$) and was the sixth most abundant species in a community of nine species of fruit bats (Wolton *et al.* 1982). On Bioko I., between 0 and 400 m, represented 13.0% of the catch of four sub-canopy species of fruit bats ($n = 332$) (Juste & Perez del Val 1995).

Adaptations By day, usually roosts hanging from vegetation; has been found between plantain leaves and in trees or bushes, sometimes at the forest edge (Hayman 1946a, Kuhn 1961, Rosevear 1965). Recapture rate in Tãï N. P. was 23.8% ($n = 21$); much higher than in most other fruit bats at this locality. Most were recaptured from six months to one year later; two were recaptured 1.7 and 2.1 years later. All individuals (including subadults and young-adults) were recaptured less than 400 m from the initial site; most less than 250 m away. This suggests that home-ranges are very small (several hectares) and site-fidelity is unusually high for a fruit bat (J. Fahr unpubl.).

Scotonycteris zenkeri

Frequencies of captures had two distinct peaks (21:00–23:00h and 02:00–04:30h), with very few captures between midnight and 02:00h. In contrast, almost the inverse pattern was shown by *S. ophiodon* at the same locality. Captive *S. zenkeri* were active for only ca. six hours per night (Wolton *et al.* 1982). The activity was either broken up into two 3-hour periods with a 2–3 hour rest commencing around midnight, or continuous for ca. six hours. Kuhn (1968) studied the innervation of the larynx of *S. zenkeri* and concluded that the pattern in this species is basal but derived in *Epomophorus labiatus*, *Epomops buettikoferi* and *Hypsignathus monstrosus*.

Foraging and Food Frugivorous. Data regarding vertical preference are equivocal. Eisentraut (1959) and Fedden & Macleod (1986) caught *S. zenkeri* mainly in elevated mist-nets. Cosson (1995) and Happold & Happold (1978), using only mist-nets at ground-level, caught *S. zenkeri* in the understorey. The latter authors suggested that foraging is more likely to occur in the upper strata and canopy. However, captures in mist-nets set from 0 to 25 m above ground in Tãï N. P. suggest that foraging occurs from ground to canopy level (median capture height 15.4 [1.5–23.6] m, $n = 21$) (J. Fahr unpubl.). Diet almost unknown. Eisentraut (1959) noted a honey-like smell when examining the stomach of a specimen but could not identify the ingested food. At Mt Nimba, this bat fed extensively on *Solanum torvum* and *S. erianthum* between Jul and Sep (Wolton *et al.* 1982). Captive individuals (in Gabon) refused various fruits, honey-water and flowers (Brosset 1966). Captive individuals (in Liberia) spent 2–2.5 h/night feeding; the mean \pm S.D. nightly fruit consumption was 20.3 ± 9.7 g ($n = 11$); the dry weight assimilated was 90%; the mean consumption per unit body weight was $0.99 \text{ g/g}^{\text{bw}}$ and the through-put time was 24 ± 8 min (Wolton *et al.* 1982). The ratio between body and intestine length is 1 : 3.6 and the intestine is rather short compared to that of other (mainly) frugivorous pteropodids (Eisentraut 1959).

Social and Reproductive Behaviour Usually roosts singly. In Gabon, Brosset (1966) caught three ♀♀, each accompanied by volant young, which were almost the same size as their mothers; later, in captivity, these young huddled with their mothers. According to Wolton *et al.* (1982), captive ♀♀ appear to be more active and more vocal than ♂♂. They emitted an abrupt high-pitched whistle throughout the night, with maximum frequency just before dawn. Adult ♂♂ in Tai N. P. had a remarkably strong and spicy scent.

Reproduction and Population Structure Litter-size: one (n = 7), two (n = 1) (Jeffrey 1975, Wolton *et al.* 1982, J. Fahr unpubl.). Embryos are implanted in both uterine horns. In West Africa (E Liberia, Côte d'Ivoire, SW Ghana) the reproductive chronology is probably seasonal bimodal monoestry: out of 70 adult ♀♀, pregnancies have been recorded for Jan and Feb (n = 7) and from Jul to Nov (n = 12), with peaks in Feb (37.5% of 16 ♀♀) and between Sep (60% of 5 ♀♀) and Oct (83.3% of 5 ♀♀). In the same region, lactating ♀♀ were found from Feb to Apr (n = 5) and from Oct to Dec (n = 5); notably, none of 10 ♀♀ was lactating in Jan (Kuhn 1961, Wolton *et al.* 1982, J. Fahr unpubl., IRSN, SMF, SMNS, USNM). None of the 29 reproductively active ♀♀ was simultaneously palpably pregnant and lactating, which suggests that the chronology is not polyoestry. In the rainforest region of West Africa, the first lactation period (Feb–Apr) would correspond to the onset of the wet season while the second period (Oct–Dec) would be at the end of the wet and start of the dry season, possibly coinciding with peaks in fruit production. Data from central Africa are inconclusive: in SW Cameroon, a ♀ was pregnant with a pea-sized embryo in Feb, and another ♀ was pregnant in Oct on Bioko I. (Eisentraut 1973a). In the Ituri region of DR Congo (near Epulu: 01° 23' N) a ♀ had an embryo (CR: 15 mm) in Jun (FMNH).

The ratio of ♂♂ to ♀♀ in 75 bats captured at Tai N. P. was 1 : 0.8 (J. Fahr unpubl.); the ratio in 16 bats captured on Bioko I. was 1 : 0.8 (Eisentraut 1973a), and the ratio in 22 museum specimens was 1 : 1.

Predators, Parasites and Diseases Two specimens were recovered from green mambas (*Dendroaspis jamesoni*) in Niger Delta, Nigeria (Luiselli *et al.* 2000). No other information.

Conservation IUCN Category: Least Concern.

Although this species probably depends on undisturbed forest to a lesser degree than *S. ophiodon*, it is most likely to be lost from areas with extensive clearings and land conversion. Population size unknown but decline inferred from loss of habitat, degradation and fragmentation. Recent records are mostly from undisturbed sites.

Measurements

Scotonycteris zenkeri

FA (♂♂): 50.3 (47–55) mm, n = 25

FA (♀♀): 52.2 (47–55) mm, n = 21

WS (c): 346 (330–372) mm, n = 10

HB: 77.5 (65–85) mm, n = 37

T: 0 mm

E: 14.4 (12–17) mm, n = 38

Tib: 20.5 (18–24) mm, n = 11

HF: 12.7 (11–14) mm, n = 33

WT: 20.3 (16–24) g, n = 59

GLS: 25.9 (24.0–27.4) mm, n = 16

GWS: 16.9 (15.9–17.8) mm, n = 17

C–M¹: 8.4 (7.9–9.0) mm, n = 18

Family RHINOLOPHIDAE

HORSESHOE BATS

Rhinolophidae Gray, 1825. Zool. Journ., 2 (6): 242.

| | | |
|---------------------------------|----------------|--------|
| <i>Rhinolophus</i> (27 species) | Horseshoe Bats | p. 303 |
|---------------------------------|----------------|--------|

This is a monotypic family, which is widely distributed in the tropical and sub-tropical regions of the Old World, with some species extending into temperate regions. All rhinolophids belong to the genus *Rhinolophus*. Currently, 77 extant species are recognized, of which 27 occur in Africa (Simmons 2005). Some of these contain subspecies that almost certainly should have specific rank. Rhinolophids have a large, complex noseleaf, the anterior component of which roughly resembles the underside of a horse's hoof and is referred to as the horseshoe (Figure 49b). The posterior part of the noseleaf has a single, erect, pointed tip. Rhinolophids have large leaf-shaped ears without a tragus, toes with three phalanges, and a medium-length tail that is completely enclosed by an interfemoral membrane (Figures 33b and 55). Rhinolophids resemble hipposiderids (which are closely related) but differ externally in the form of the noseleaf and the number of phalanges in the toes. None are considered to be pests.

Rhinolophids are small to medium-sized microbats with long, soft, dense fluffy pelage. Most African rhinolophids are greyish-fawn or greyish-brown in their grey-phase, and have an orange-phase. They have a small compact body and a rounded head with a short blunt muzzle. The ears are almost as broad as they are long and are well separated; the antitragus is conspicuous and there is no tragus. The eyes are very small. The noseleaf is very prominent and is comprised of an anterior horseshoe-shaped component (the horseshoe), a central component, which has a transverse projection (the sella)

and a longitudinal connecting process, and a subtriangular posterior component with an erect tip referred to as the lancet (Figure 56). Many species of rhinolophids are distinguished by the shape of the lancet, sella and connecting process. The wings are large and broad with rounded tips; the second finger has a long metacarpal but no bony phalanges. The hindlimbs are moderately long with small soles and relatively long toes, each (except the hallux) having three phalanges (cf. two in hipposiderids). The tail is relatively short to medium (30–37% of TL), and is completely enclosed by the interfemoral membrane; calcars are present. Females have one pair of pectoral nipples and one pair of pubic nipples; the ♂♂ of some species have a false nipple and tuft of stiff hairs (axillary tuft) in each armpit. The skull (Figure 57) has nasal swellings (sometimes called rostral swellings or rostral inflations), a low sagittal crest (usually more prominent anteriorly than posteriorly) and no postorbital processes. Supraorbital ridges vary from weak to prominent. The nasal branches of the premaxillae are lost. The palatal branches are reduced, partly cartilaginous, not fused with each other and not fused with the maxillary; they are usually lost when skulls are cleaned. Because of this, greatest length of skull (GLS) of rhinolophid bats is replaced by CrnC (the distance from the anterior of the upper canine to the most posterior part of the skull). The palate has a very deep, wide, roughly U-shaped anterior palatal emargination, and also a U-shaped posterior emargination, and is shorter than it is broad. The length of the palate between the two emarginations is referred to as the length of the palatal bridge. The tympanic bullae are relatively small

Figure 55. Characters of African bats in the family Rhinolophidae. (a) Flight membranes and bones of wing, hindlimb and tail (e.g. *Rhinolophus blasii*). (b) Ventral view of armpit showing axillary tuft (e.g. *R. alcyone*; based on Rosevear 1965). (c) Ear with 11 internal folds, a large antitragus but no tragus (e.g. *R. ziama*; based on photo by T. Vierhaus). Grooves in the lower lip: (d) one well-defined median groove and no lateral grooves (e.g. *R. eloquens*, (e) one well-defined median groove and one poorly-defined lateral groove on each side (e.g. *R. alcyone*) and (f) three well-defined grooves (e.g. *R. simulator*).

Figure 56. (a) Lateral and (b) frontal views of a noseleaf of *Rhinolophus* showing the components as defined and referred to in the profiles below (some components are defined differently by some other authors).

but the cochleae are well developed. The dental formula is variable, usually $^{1123}/_{2133} = 32$. However, the anterior upper premolar and/or the posterior middle premolar may be missing. In some species, the anterior upper premolar lies within the toothrow (albeit sometimes slightly displaced) and separates the canine from the posterior premolar: in other species, this tooth is fully displaced labially and the canine and posterior premolar are in contact. Similarly, the middle lower premolar may be within the toothrow or partly or fully displaced labially, or it may be absent, and the anterior and posterior

lower premolars may be separated or in contact accordingly. The upper incisors are very small; the lower incisors are tricuspid. The molariform teeth do not show any particular modification; M^3 almost always has three ridges (Csorba *et al.* 2003).

Most African rhinolophids have low to very low aspect ratios and low to very low wing-loadings; only one species is known to have medium wing-loading. They fly slowly with considerable manoeuvrability. They can hover briefly and take off from the ground. Rhinolophids are insectivorous: several feed mainly on moths and/or small beetles, at least during some seasons. Some forage by slow-hawking, and some are predominantly fly-catchers and/or gleaners that often forage within 6 m of the ground, often close to foliage and tree-trunks, in cluttered environments. At least one species catches flying insects in the tip of one wing, bending the phalanges to hold the prey before rapidly transferring it to the mouth (Webster & Griffin 1962). Rhinolophids do not 'pouch' their prey in the interfemoral membrane (cf. vespertilionids). They sometimes fly into lighted rooms in search of prey. Most forage alone. Their echolocation calls are typically FM/CF/FM calls with a sustained CF component and maximum energy in the second harmonic: some (perhaps all) species in Africa can be distinguished by the CF-frequency of their calls (Figure 58). The echolocation calls of rhinolophids are adapted to facilitate the detection of flutter (by exploiting Doppler-shifted echoes reflected from the fluttering wings of insects), and are particularly suitable for densely cluttered environments (Neuweiler 1989). Harmonics are of particular value to bats that emit long CF calls. The calls, which initially include the fundamental harmonic, are produced in the larynx, and the nasal swellings (swellings in the skull beneath the noseleaf) facilitate the production of harmonics and suppress the fundamental harmonic in the emitted sound (Suthers *et al.* 1988). Tracheal chambers suppress the fundamental harmonic in internally reflected sound, and this may enable rhinolophids to rely on the tissue-conducted fundamental as a reference or marker of their own laryngeal generated sound, which could be useful in processing sonar information (Suthers *et al.* 1988). Rhinolophids emit their echolocation calls through the nostrils and the noseleaf acts as a parabolic reflector to direct a beam of sound in front of the bat and shield the ears, to some extent, from the emitted sounds

Figure 57. *Rhinolophus hildebrandtii*. Skull (RMCA RG 23816).

Figure 58. Sonograms of the FM/CF/FM echolocation calls of seven species of *Rhinolophus* from Malawi, presented in order of decreasing CF frequency: all bats hand-held (M. Happold unpubl.). (a) *R. swinnyi*, (b) *R. blasii*, (c) *R. simulator*, (d) *R. clivosus*, (e) *R. fumigatus*, (f) *R. ? eloquens* and (g) *R. hildebrandtii*. Time axis marked at intervals of 50 ms.

(Möhres 1953). While echolocating, the ears move independently with a very characteristic flickering movement, and the head moves up and down and from side to side to beam the sound in different directions.

Rhinolophids are unable to scuttle over the ground, and they cannot climb. During the day, most roost in dark caves or cave-like day-roosts such as mine-adits, hollow trees and dark places in buildings. They hang freely from ceilings or hang in contact with vertical walls. When hanging, the tail and interfemoral membrane fold up over the back and the wings fold around the chest so the body is either mostly or fully enclosed by the flight-membranes. Rhinolophids roost singly or in small to very large groups. Very little is known about the social behaviour of African species. Maternity colonies are established by many species. When ♂ and ♀ *R. ferrumequinum* begin to roost together at the end of summer, the ♂♂ become territorial and establish small harems (see profile); the mating systems of other species in Africa are apparently not known. All of the seven African rhinolophids for which data are available are monotocous and seasonally monoestrous. Delayed fertilization and sperm storage has been documented for *R. capensis*, *R. clivosus*, *R. ferrumequinum* and *R. hipposideros*, delayed implantation for *R. landeri* and retarded embryonic development for *R. ferrumequinum* (in Europe) (see species profiles). In temperate regions, rhinolophids mate in autumn, sperm storage and hibernation occur during winter, and ovulation followed by uninterrupted gestation occurs in spring. In the tropics, young are born at the end of the dry season or in the wet season (data available for five species). It is thought that the young cling to the pubic nipples with their toes and to the pectoral nipples with their teeth. Females carry their young while flying from perch to perch within a day-roost, and will carry the young away from a disturbed day-roost, but they probably do not carry their young while routinely foraging for food.

The geological range of the Rhinolophidae is late Eocene to Recent in Europe, Miocene to Recent in Africa, early Miocene to Recent in Asia, middle Miocene to Recent in Australia and Recent in other regions now occupied (Bogdanowicz & Owen 1992, Corbet & Hill 1992, Csorba *et al.* 2003). The Rhinolophidae had probably diverged

from the Hipposideridae by the late Eocene (Csorba *et al.* 2003). According to Bogdanowicz & Owen (1992), the family probably originated in the Old World tropics, perhaps in Africa or perhaps in southern Asia. Maree & Grant (1997) also agree that morphological analyses indicate that the family probably originated in South-East Asia. In contrast, a European origin for the family, and monophyly for the African and Palaearctic species is proposed by Csorba *et al.* (2003). Based on genetic evidence, Csorba *et al.* (2003) suggest that there was an early emergence of a clade containing *R. trifoliatum* and *R. hipposideros* (of which only *R. hipposideros* occurs in Africa), and a clade containing, amongst others, an African clade, which probably contains all of the other African species. Within this African clade, the clade representing the most basal lineage comprises species linked to rainforest habitat (*R. alcyone*, *R. landeri* and probably *R. guineensis*). Subsequently, there seems to have been a series of radiations into dry environments. The first of these radiations seems to have given rise to a Mediterranean group (*R. blasii*, *R. euryale* and *R. mehelyi*) and *R. blasii* appears to have migrated southwards as far as southern Africa more recently. Subsequently, there appear to have been at least two radiations in arid areas of eastern and southern Africa, one giving rise to a lineage including *R. capensis*, *R. denti*, *R. simulator* and *R. swinnyi* (Maree & Grant 1997) and probably also *R. adami* and *R. maendeleo* (Csorba *et al.* 2003), and another giving rise to a lineage containing *R. clivosus*, *R. darlingi*, *R. fumigatus* and *R. hildebrandtii* (Maree & Grant 1997) and also *R. ferrumequinum*, *R. maclaudi* and *R. eloquens* (Csorba *et al.* 2003).

Rhinolophids have radiated into forests, woodlands and semi-desert habitats at both high and low altitudes. The majority of species are tropical or sub-tropical and a few occur in temperate regions. Of the 27 species that occur in Africa, 14 are found only in the tropics, four are found only in temperate regions and seven are in tropical, sub-tropical and temperate regions. Seven species are only or mainly found in forest habitats, nine occur in both forests and savannas, four occur only in savannas, one occurs in both savanna and arid habitats, three occur in all of these habitats, and three which are found in the Mediterranean Coastal BZ extend marginally into the arid habitats of the Sahara Arid BZ. Thirteen species (48%) have been found in montane habitats but,

of these, only *R. ruwenzorii* and the very closely related *R. hilli* are found only in montane habitats. It is not uncommon to find two species at any one locality, but the occurrence of three or more species seems to be very rare (except in Malawi where 3–5 species have been recorded at six localities Happold & Happold 1997). Some examples are:

Misserghin, Algeria (garrigue): *R. blasii*, *R. ferrumequinum*, *R. hipposideros* and *R. mehelyi* (Kowalski & Rzebik-Kowalska 1991).

Shimoni, Kenya (coastal forest mosaic): *R. fumigatus*, *R. deckenii* and *R. landeri* (Aggundey & Schlitter 1984).

Liwonde N. P., Malawi (miombo woodland): *R. blasii*, *R. clivosus*, *R. fumigatus*, *R. hildebrandtii* and *R. simulator* (Happold & Happold 1997).

Based on morphological data, the family Rhinolophidae was placed in the superfamily Rhinolophoidea with the families Nycteridae, Megadermatidae and the very closely related Hipposideridae

(Simmons 1998, Simmons & Geisler 1998), but more recent molecular studies have contradicted many groupings based on morphological data and, pending resolution of the controversies, no chiropteran superfamilies are recognized by Simmons (2005). Some authors, including Koopman (1984, 1993, 1994) and Simmons (1998), follow Tate (1941) in considering the Rhinolophidae to include the Hipposideridae as a subfamily. However, the familial status of the Hipposideridae has been retained by Maree & Grant (1997), Csorba *et al.* (2003), Simmons (2005) and in the majority of books about African mammals and is retained here. For further comment, see Family Hipposideridae.

The Rhinolophidae have been comprehensively reviewed by Csorba *et al.* (2003). All rhinolophids belong to the genus *Rhinolophus*.

Meredith Happold & F. P. D. Cotterill

GENUS *Rhinolophus*

Horseshoe Bats

Rhinolophus Lacépède, 1799. Tabl. Div. Subd. Orders Genres Mammifères, p. 15. Type species: *Vespertilio ferrum-equinum* Schreber, 1774.

This genus currently has 77 species of which 27 occur in Africa (Simmons 2005). There are no other genera in the family Rhinolophidae and the characters of this genus are given in the family profile.

This genus is divided into 15 species-groups following Csorba *et al.* (2003) (see also Bogdanowicz 1992, Bogdanowicz & Owen 1992, Maree & Grant 1997, Fahr *et al.* 2002). Of these groups, eight are represented in Africa:

Figure 59. Variations in the shape of the connecting process of the noseleaf of African *Rhinolophus*. (a) Noseleaf showing (black) that part of the connecting process that is described by the following terms. Rounded as in (b) *R. maendeleo* (based on Kock *et al.* 2000), (c) *R. adami* (based on Kock *et al.* 2000), (d) *R. simulator* (M. Happold, Malawi) and (e) *R. clivosus* (M. Happold, Malawi). Subtriangular as in (f) *R. landeri* (based on Csorba *et al.* 2003), (g) *R. guineensis* (based on Csorba *et al.* 2003), (h) *R. alcyone* (based on Csorba *et al.* 2003) and (i) *R. mehelyi* (based on Csorba *et al.* 2003). Rising to a high horn as in (j) *R. blasii* (M. Happold, Malawi) and (k) *R. euryale* (based on Gaisler 2001a). Rounded but rising to a high peak as in (l) *R. sakejiensis* (based on Csorba *et al.* 2003). Very low, slightly rounded or flat as in (m) *R. hipposideros* (based on Csorba *et al.* 2003). Greatly reduced, very low and concave as in (n) *R. ziama* (from photo in Fahr *et al.* 2002).

*Rhinolophus hildebrandtii*.

adami group: two species – *R. adami*, and *R. maendeleo*.

capensis group: four species – *R. capensis*, *R. denti*, *R. simulator* and *R. swinnyi*.

euryle group: two species – *R. euryle* and *R. mehelyi*.

ferrumequinum group: eight species including *R. clivosus*, *R. darlingi*, *R. deckenii*, *R. ferrumequinum*, *R. hillorum*, *R. sakejiensis* and *R. silvestris*.

fumigatus group: three species – *R. eloquens*, *R. fumigatus* and *R. hildebrandtii*.

hipposideros group: one species – *R. hipposideros*.

landeri group: four species – *R. alcyone*, *R. blasii*, *R. guineensis* and *R. landeri*.

maclaudi group: four species – *R. hilli*, *R. maclaudi*, *R. ruwenzorii* and *R. ziama*.

The African species are distinguished mainly on the basis of the following characters (Table 14):

Table 14. Key to the African species in the family Rhinolophidae. Information from African material, mostly from species profiles. Sample sizes of *R. adami*, *R. hilli*, *R. maendeleo*, *R. sakejiensis*, *R. silvestris* and *R. ziama* are less than six. Distinguishing species that are morphologically very similar from the information below is not easy, and identifications should be confirmed using the additional information in the Description, Similar Species and Distribution sections of the species profiles.

| Connecting process | Position of anterior upper premolar ^a
(Proximity of canine and posterior premolar) | Sella ^b
Hairiness and shape | Lancet | Horseshoe mean (range) (mm) | |
|--------------------|---|--|---|-----------------------------|--|
| Rounded | Within toothrow
(Well separated) | Naked
Sides slightly concave | Subtriangular, sides slightly convex
Tip broad and rounded | 8.5, 9.0 | |
| Rounded | Within toothrow
(Well separated) | Naked
Sides concave | Subtriangular, sides slightly concave
Tip bluntly pointed | 8.2, 8.4 | |
| Rounded | Within toothrow
(Well separated) | Naked
Almost parallel-sided or slightly concave | Subtriangular, sides slightly concave
Tip bluntly pointed | 7.1 (6.8–7.5) | |
| Rounded | Within toothrow
(Well separated) | Naked
Sides slightly concave | Subtriangular, almost hastate, sides concave
Tip bluntly pointed | 6.8 (6.0–7.4) | |
| Rounded | Within toothrow
(Well separated) | Naked
Sides slightly concave | Subtriangular or hastate
Tip somewhat rounded | 7.4 (6.7–9.0) | |
| Rounded | Usually partly displaced, sometimes fully displaced
(Typically well separated, never in contact) | Naked
Sides parallel or slightly concave | Hastate
Tip bluntly pointed | 7.7 (7.3–8.1) | |
| Rounded | Usually fully displaced or absent
(Separated by very narrow gap) | Naked
Sides parallel or slightly concave | Subtriangular, sides almost straight
Tip bluntly pointed | 10.3 (9.1–11.5) | |
| Rounded | Fully displaced
(In contact or almost so) | Naked
Sides concave | Subtriangular, sides slightly concave
Tip bluntly pointed | 9.5, 10 | |
| Rounded | Fully displaced or absent
(In contact) | Naked
Sides concave | Subtriangular, sides slightly concave
Tip bluntly pointed | 8.0 (7.1–8.7) | |
| Rounded | Fully displaced or absent
(In contact) | Naked
Sides slightly concave | Hastate
Tip bluntly pointed | 8.1 (7.0–9.0) | |
| Rounded | Fully displaced or absent
(In contact) | Naked
Sides concave | Hastate
Tip rounded | 7.8 (6.6–9.6) | |

Connecting process. Can be rounded (with variable height relative to the height of the sella), rounded but rising to a high peak, rising to a high horn (not rounded), subtriangular, or greatly reduced (Figure 59).

Position of the anterior upper premolar. Can be within the toothrow (so canine and posterior premolar are well separated), or fully displaced labially (so canine and posterior premolar are in contact) or partly displaced labially (so canine and posterior premolar are almost in contact). It is only the cingula of the canine and premolar that are ever in contact. The anterior upper premolar is, or can be, absent in some species (Figure 62).

Sella. Can be hairy (well covered by longish, moderately conspicuous hairs) or naked (sparsely covered by inconspicuous short hairs). The shape of the sella is variable (Figure 60).

Lancet. Can be subtriangular, subtriangular with slightly convex sides, subtriangular with slightly concave sides, hastate (having a broad base, markedly concave sides and narrow tip), or short, very narrow and almost parallel-sided (Figure 61). The tip of the lancet can be bluntly pointed or broader and more rounded.

Greatest breadth of horseshoe.

Relative length of first phalanx of the fourth finger to the metacarpal of the fourth finger. Said to be relatively short if its mean relative length is less than 22% of the metacarpal, medium if its mean relative length is 22–25% of the metacarpal, and long if its mean relative length is >25%.

Length of forearm, tibia and ear.

Relative length of palatal bridge. This is the distance from anterior emargination to posterior emargination along mid-line of the bony palate, excluding the median spike projecting from the posterior margin (Figure 23g); expressed as a percentage of $C-M^3$. Said to be short if less than 30%, medium if 31–37%, and long if >37% (all data from Csorba *et al.* 2003).

Axillary tuft. Present (Figure 55b) or absent.

Ear folds. This is the number of internal folds in the outer side of the pinna (Figure 55c). Particularly relevant to species in the *maclaudi* group.

| | First phalanx of fourth finger as % of 4th metacarpal: category ^c , mean (range) | FA mean (range) (mm) | Tib mean (range) (mm) | E mean (range) (mm) | Miscellaneous | Species |

| Rounded | Fully displaced or absent
(In contact or almost so) | Hairy
Upper two-thirds parallel-sided | Subtriangular, sides slightly concave
Tip rounded | 11.6 (11.1–12.3) | |
| Rounded | Fully displaced or absent
(In contact) | Hairy
Sides parallel or slightly concave | Subtriangular, sides slightly concave
Tip rounded | 10.3 (9.6–11.5) | |
| Rounded but rising to high narrow peak | Absent (n = 3)
(In contact) | Naked
Sides slightly concave | Hastate
Tip long, narrow, bluntly pointed | ca. 10–11 | |
| Rising to high horn | Within tooththrow
(Well separated) | Naked
Wedge-shaped, top narrow | Subtriangular or hastate
Tip rounded | 8.1 (7.2–9.0) | |
| Rising to high horn | Within tooththrow
(Well separated) | Naked
Parallel-sided, top broad, rounded | Subtriangular
Tip bluntly pointed | 7.2 (6.5–7.5) | |
| Subtriangular | Somewhat displaced
(Separated) | Naked
Parallel-sided | Hastate, upper half narrow and almost parallel-sided
Tip bluntly pointed | 6.4 (4.9–7.5) | |
| Subtriangular | Within tooththrow
(Well separated) | Naked
Sides slightly concave | Hastate
Tip bluntly pointed | 7.2 (6.0–8.0) | |
| Subtriangular | Within tooththrow
(Well separated) | Naked
Parallel-sided | Hastate
Tip bluntly pointed | 8.6 (8.3–9.3) | |
| Subtriangular | Within tooththrow
(Well separated) | Naked
Parallel-sided | Subtriangular, sides straight or slightly concave
Tip bluntly pointed | 10.0 (8.3–11.2) | |
| Very low, slightly rounded or flat | Within tooththrow
(Well separated) | Naked
Long, narrow, wedge-shaped | Subtriangular, sides slightly concave
Tip bluntly pointed | 6.6 (6.1–7.1) | |
| Greatly reduced, very low, concave | Within tooththrow or slightly displaced
(Separated) | Naked
Inclined forward, sides almost parallel, basal lobes very large | Subtriangular, moderately tall
Tip pointed | 15.0, 16.0
– | |
| Greatly reduced, very low, concave | Within tooththrow
(Separated) | Hairiness not known
Inclined forward, sides almost parallel, basal lobes very large | Almost parallel-sided, moderately tall
Tip moderately broad and rounded | ca. 11.5 | |
| Greatly reduced, very low, concave | Within tooththrow or slightly displaced
(Separated) | Naked
Upright, sides concave, basal lobes very large | Subtriangular, moderately tall
Tip truncated | 11.9 (10.8–12.6) | |
| Greatly reduced, very low, concave | Displaced
(Almost in contact) | Naked
Upright, sides concave, basal lobes very large | Subtriangular, tall
Tip bluntly pointed | 12 | |

^aThe anterior upper premolar is said to be ‘within tooththrow’ if it lies in the middle of the tooththrow or is only slightly displaced labially, causing the canine and posterior upper premolar to be distinctly separated.

^bThe sella is said to be naked unless it is well covered by longish and fairly conspicuous hairs (as opposed to inconspicuous short hairs).

^cThe first phalanx of the fourth finger varies in its length relative to that of the fourth metacarpal: it is said to be ‘short’ if its mean relative length is less than 22% of the metacarpal, ‘medium’ if its mean relative length is 22–25% of the metacarpal, and ‘long’ if its mean relative length is >25%.

^dNo mean given; sample size not known.

Figure 60. Variations in the shape of the sella in African *Rhinolophus*. (a) Frontal view of the noseleaf showing the relevant part of the sella (shaded). The sella can be described as (b) almost parallel-sided (e.g. *R. alcyone*; based on Rosevear 1965), (c) with upper two-thirds parallel-sided (e.g. *R. hildebrandtii*; M. Happold, Malawi), (d) concave sided (e.g. *R. clivosus*; M. Happold, Malawi), (e) wedge-shaped (e.g. *R. blasii empusa*; M. Happold, Malawi) or (f) parallel-sided with greatly expanded narial lobes (e.g. *R. ziama*; based on Fahr *et al.* 2002). Sellas which curve forwards have been pushed back to flatten the anterior surface and reveal its outline.

Figure 61. Variations in the shape of the lancet in African *Rhinolophus*. (a) Frontal view of the noseleaf showing the lancet (shaded). The lancet can be (b) subtriangular (e.g. *R. deckenii*; based on Csorba *et al.* 2003), (c) subtriangular with slightly convex sides (e.g. *R. adami*; based on Kock *et al.* 2000), (d) subtriangular with slightly concave sides (e.g. *R. maendeleo*; based on Kock *et al.* 2000), (e) hastate (e.g. *R. ferrumequinum*; based on Csorba *et al.* 2003), or (f) short, very narrow and almost parallel-sided (e.g. *R. hillorum*).

Distribution. Some species are extremely similar morphometrically, and are best distinguished by their distributions. The validity of the specific status of some of these species is uncertain.

Additional diagnostic characters include:

Cranio-canine length (CrnC). For *Rhinolophus*, the distance from the anterior of the upper canine to the most posterior part of the skull (Figure 23f) is used instead of GLS. This is because the nasal branches

of the premaxillae are absent and the palatal branches are frequently lost during preparation of the skulls of these bats.

Zygomatic width relative to mastoid width. Zygomatic width ranges from much greater than mastoid width to much narrower than mastoid width (see Figure 63b and c for same character in Hipposideridae).

Lateral leaflets (on each side of horseshoe). Can be present, rudimentary (inconspicuous) or absent.

Number of grooves in the chin region of the lower lip. There is invariably a well-defined median groove. Lateral grooves (one on each side of the median groove) can be well defined, indistinct or absent (Figure 55d–f).

Median emargination in horseshoe. Can be present (deep to shallow) or absent.

Frontal and lateral views of the noseleaf, lateral views of the rostral part of the skull, and occlusal views of the upper canine and premolars, are given for almost all African species in Csorba *et al.* (2003).

The species are presented in alphabetical order irrespective of the species-group to which they belong.

Meredith Happold

Figure 62. Variations in the size and position of the upper premolars in African *Rhinolophus*. *Left*: occlusal views of teeth on left side of upper jaw. *Right*: lateral views of labial side of the same teeth. The anterior upper premolar can be (a) within the toothrow so canine and posterior premolar are well separated (e.g. *R. denti*), (b) partly displaced labially so canine and posterior premolar are almost in contact (e.g. *R. hilli*), (c) fully displaced labially so canine and posterior premolar are in contact (e.g. this specimen of *R. fumigatus*), or (d) absent (e.g. this specimen of *R. hildebrandtii*).

Rhinolophus adami ADAM'S HORSESHOE BAT

Fr. Rhinolophe du Congo; Ger. Adams Hufeisennase

Rhinolophus adami Aellen and Brosset, 1968. Rev. Suisse Zool. 75: 443. Grotte de Kimanika, Kouilou, Congo.

Taxonomy Species-group: *adami* (with *R. maendeleo*). Appears closely related to *R. maendeleo* (Kock *et al.* 2000). Synonyms: none. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar within toothrow; connecting process rounded and comparatively high; lancet subtriangular with slightly convex sides; sella with slightly concave sides and top which curves acutely forward and slightly downward; horseshoe breadth 8.5–9.0 mm. Sexual dimorphism: no information. Dorsal pelage brownish. Ventral pelage brownish-grey, sometimes becoming whitish on lower abdomen. Orange-phase: no information. Axillary tufts: no information. Ears comparatively and relatively of medium length (25–26 mm, 51–53% of FA), brown with darker rims. Noseleaf with lancet long, subtriangular with rounded tip, sides convex (Figure 61c) or almost so (cf. *R. maendeleo*). Connecting

process well developed, smoothly rounded, rising higher than sella. Sella naked, large and broad, sides slightly concave, top curving acutely forward and slightly downward. Basal lobes of sella poorly developed but surrounding a well-developed narial cup. Horseshoe narrow (8.5, 9.0 mm); almost covering muzzle; no lateral leaflets; median emargination well defined. Lower lip with three grooves. Wings dark brown; first phalanx of fourth finger of medium relative length (23% of fourth metacarpal, $n = 2$). Tibia 38–40% of FA ($n = 2$). Baculum with basal cone short with shallow dorsal and ventral invaginations (cf. *R. maendeleo*); shaft becoming dorsoventrally flattened distally; tip not expanded (Kock *et al.* 2000).

Skull narrow; zygomatic width much less than mastoid width. Rostrum with anterior median swellings well developed, posterior swellings reduced (Csorba *et al.* 2003). Frontal depression moderately deep. Sagittal crest low. Infraorbital foramen covered by bony bar (cf. *R. maendeleo*). Palatal bridge 2.8–3.0 mm, 42–44% of $C-M^3$. Anterior upper premolar small, within toothrow; canine and

posterior premolar well separated. Middle lower premolar slightly displaced labially; anterior and posterior lower premolars separated. Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation None known.

Similar Species Five other *Rhinolophus* in Africa have the anterior upper premolar in the toothrow and a rounded connecting process, but none are known to be sympatric with *R. adami*:

Rhinolophus maendeleo. Lancet subtriangular with slightly concave sides; connecting process rising only just above sella; sella with markedly concave sides, top of sella curving obtusely forward; horseshoe narrower (8.2, 8.4 mm). Skull with infraorbital foramen open; palatal bridge 37–39% of C–M³.

R. simulator simulator. Ears shorter (18–23 mm). Lancet hastate, horseshoe narrower (6.7–8.3 mm). Palatal bridge relatively short (29–34% of C–M³).

R. swinnyi. Smaller (FA: 40–44 mm). Lancet hastate, horseshoe narrower (6.8–7.4 mm).

R. denti. Smaller (FA: 37–44 mm). Horseshoe narrower (6.8–7.5 mm).

R. capensis. Horseshoe narrower (7.3–8.1 mm).

Distribution Endemic to Africa. Known only from the type locality, Kouilou, Congo, in the Rainforest–Savanna Mosaic very near the Rainforest BZ.

Habitat The vegetation of the Kouilou region is a mosaic of lowland rainforest and secondary grassland, and limestone caves are present.

Abundance Only four specimens were described by Aellen & Brosset (1968): these, and an additional seven specimens (six in

MNHN, one in HNHM) recognized by Kock *et al.* (2000), appear to be the only known specimens. Probably very rare (see Conservation).

Remarks The holotype, an adult ♀, and two subadult ♀♀ were collected on the same day in a limestone cave (Grotte de Kimanika) for which no details are available (Aellen & Brosset 1968). A fourth specimen, an adult ♂, was collected in another limestone cave (Grotte de Meya-Nzouari), parts of which were dry and ‘dead’ with respect to the growth of limestone formations, and parts of which were still ‘living’ and very humid, with water seeping over the formations and trickling into underground streams (Adam & Le Pont 1974). This cave was also inhabited by *Rousettus aegyptiacus*, *Rhinolophus silvestris*, *Hipposideros ruber*, *H. gigas*, *Triaenops afer* and *Miniopterus minor*.

Predators, Parasites and Diseases Ectoparasites include a bat-fly *Penicillidia penicillidia* (Diptera: Nycteribiidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Data Deficient.

Known from only four specimens from only two of 45 caves investigated for the presence of bats over a period of ca. seven years (Adam & Le Pont 1974), and an additional seven specimens from the type locality (Kock *et al.* 2000). Furthermore, not recorded from ten localities in nearby Mayombe and Lower Kouilou regions of Congo, where 80 specimens (14 species) were collected by Dowsett *et al.* (1991). Also, not recorded from Haut-Ivindo region of Gabon where 1732 individuals belonging to 27 species were captured from caves and by mist-netting by Brosset (1966), nor from Kikwit (05° 13'S, 18° 49'E, DR Congo) where 538 bats belonging to 18 species were collected in 1995 (Van Cakenberghe *et al.* 1999). As indicated by Dowsett *et al.* (1991), this species is potentially at risk because it roosts in caves occupied by the fruit bat *Rousettus aegyptiacus*, which is sometimes hunted for food.

Measurements

Rhinolophus adami

FA: 46–50 mm, n = ?*

Rhinolophus adami

Rhinolophus alcyone HALCYON HORSESHOE BAT

Fr. *Rhinolophe alcyon*; Ger. Temmincks Hufeisennase

Rhinolophus alcyone Temminck, 1852. Esquisses Zool. sur la Côte de Guinée, p. 80. Boutry River, Ghana.

Taxonomy Species-group: *landeri*. Synonyms: none. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar within tooththrow; connecting process triangular; lancet subtriangular; sella parallel-sided; first phalanx of fourth finger relatively short; axillary tufts orange-red (if present); tibia 24 (21–27) mm. Sexes similar. Pelage dense, soft, fluffy; mid-dorsal hairs ca. 9 mm. Dorsal pelage dark to medium brown; hairs yellowish-beige with brown at tip. Ventral pelage slightly paler. Orange-phase: dorsal pelage pale brown to bright orange-red. Adult ♂♂ often with orange-red or brown axillary tufts. Ears comparatively and relatively short (19–25 mm, 36–49% of FA); each with 8–9 internal folds. Noseleaf with lancet subtriangular (margins straight or slightly concave), tip bluntly pointed. Sella with extremely short white hairs, narrow, with straight, almost parallel sides (Figure 60b); top rounded, curved forward. Connecting process well developed, subtriangular, with bluntly to sharply pointed tip. Horseshoe of medium breadth (8.3–11.2 mm) almost covering muzzle; lateral leaflets present, median emargination present. Lower lip with a well-defined median groove and two poorly defined lateral grooves. Wings medium to blackish-brown; first phalanx of fourth finger relatively short (20.8 [19–22]% of fourth metacarpal, $n = 20$). Interfemoral membrane paler. In one specimen (possibly abnormal) the flight-membranes are cream with dark brown reticulation (BMNH 66.6242). Tibia 46.1 (38–52)% of FA ($n = 22$).

Skull robust; zygomatic arches moderately robust; zygomatic width greater than mastoid width. Nasal swellings relatively high, anterior median swellings globular and prominent, lateral and posterior swellings medium (Csorba *et al.* 2003). Frontal depression very shallow; supraorbital ridges weak. Sagittal crest variable – low to well developed. Palatal bridge 29–35% of C–M³. Anterior upper premolar within tooththrow or only slightly displaced labially; canine and posterior premolar well separated. Middle lower premolar either within tooththrow or displaced labially; anterior and posterior lower premolars separated. Anterior lower premolar at least two-thirds the height of the posterior premolar. Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation No subspecies. Eisentraut (1964) reported that six specimens from Bioko I. are larger than those from the mainland (especially ear length). However, the differences are small. For example:

Bioko I.: FA: 53.5 (51–56) mm; T: 31.3 (26–38) mm; E: 24.0 (23–25) ($n = 6$).

Cameroon: FA: 52.4 (49–56) mm; T: 26.1 (22–32) mm; E: 22.0 (20–24) mm, $n = 26$.

Similar Species Only two other *Rhinolophus* in sub-Saharan Africa have the following combination of characters: anterior upper

premolar within tooththrow; connecting process triangular and pointed; first phalanx of fourth finger relatively short:

Rhinolophus landeri. Body measurements almost always smaller (FA: 35–49 mm, Tib: 17–21 mm). Skull smaller (CrnC: 16.9–19.1 mm).

R. guineensis. Body measurements usually smaller (FA: 44–50 mm, Tib: 21–22 mm). Skull smaller (CrnC: 19.2–20.6 mm). Sagittal crest less developed. Axillary tufts in ♂♂ usually white.

Distribution Endemic to Africa. Mainly recorded from the Rainforest BZ and surrounding Rainforest–Savanna Mosaics, from Guinea to Ghana, from Nigeria to Central African Republic and southwards to S Congo and Bioko I., with some apparently isolated records in NE DR Congo, S Sudan and Uganda. Also recorded from the Sudan Savanna BZ in Senegal, and the Guinea Savanna BZ in Côte d’Ivoire and Ghana. Records are scattered but this probably reflects insufficient collecting. Predicted to occur throughout the Rainforest BZ. Mapped from country checklists (see order Chiroptera), other literature and museum records.

Habitat Predominantly lowland rainforest, but also dense relict and riverine forests north of the Rainforest BZ.

Abundance Uncertain: rarely collected.

Remarks Day-roosts include caves, hollow trees and hollow logs, a mine-shaft and in the roof of a hut (Eisentraut 1956, Verschuren 1957, Rosevear 1965, Brosset 1966). Reported roosting singly and

Rhinolophus alcyone

in small groups of unknown composition (Rosevear 1965). Has been seen flying over water, swampy areas and along forest paths. Diet not known. Echolocation call-shape FM/CF/FM; CF-frequency (Uganda) 87 kHz (Pye & Roberts 1970, Roberts 1972). Litter-size: one (n = 5). Reproductive chronology not known. At ca. 6°N in Côte d'Ivoire, 4 of 4 ♀♀ were pregnant in mid-Feb (CR: 19–26 mm) (Lim & Van Coeverden de Groot 1997). Ectoparasites include bat-flies *Phthiridium inopinatum* (Diptera: Nycteribiidae), *Raymondia allisoni* (Diptera: Streblidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Rhinolophus blasii BLASIUS'S HORSESHOE BAT (PEAK-SADDLE HORSESHOE BAT)

Fr. Rhinolophe de Blasius; Ger. Blasius Hufeisennase

Rhinolophus blasii Peters, 1867. Monatsber. K. Preuss. Akad. Wiss. Berlin 1866: 17 [publ. 1867].

SE Europe; restricted to Italy by Ellerman *et al.* (1953: 59).

Taxonomy Species-group: *landeri*. Synonyms: *andreinii*, *blasiusi*, *brockmani*, *clivus* Blasius, 1857, *empusa*, *meyeroehmi*. Subspecies: four; three in Africa. Chromosome number (South Africa): 2n = 58; aFN = 60. Two pairs biarmed chromosomes, 26 pairs acrocentric chromosomes; X = large submetacentric; Y = small metacentric (Rautenbach 1986).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); small for an African rhinolophid; anterior upper premolar within tooththrow; connecting process rising to high, narrow, forward-curving pointed horn; sella wedge-shaped; horseshoe breadth 7.2–9.0 mm; no axillary tufts; first phalanx of fourth finger relatively long; no marked contrast between crown areas of anterior and posterior lower premolars. Sexes similar. Pelage dense, soft, fluffy; mid-dorsal hairs 8–9 mm. Dorsal pelage greyish-fawn to brownish-grey; hairs pale greyish-fawn or pale brownish-grey, with darker tip. Ventral pelage considerably paler. Only one individual in orange-phase has been recorded (Ansell 1974). No axillary tufts on adult ♂♂. Ears comparatively and relatively short (16–21 mm, 33–44% of FA), dark greyish-brown. Noseleaf with lancet subtriangular with slightly concave sides (sometimes hastate), tip rounded. Connecting process well developed, rising to high, narrow, pointed horn (Figure 59j). Sella naked, wedge-shaped with sides converging towards top; top narrow and tilted forward (Figure 60e). Horseshoe narrow (7.2–9.0 mm), not covering whole muzzle but on average broader than in *R. euryale*; lateral leaflets absent, rudimentary or well developed (probably depending on subspecies); median emargination present but indistinct. Lower lip with three grooves: the two lateral grooves are poorly defined in *R. b. empusa*. Wings and interfemoral membrane dark greyish-brown. First phalanx of fourth finger relatively long (25.8 [24–28]% of fourth metacarpal, n = 30) and usually >50% of second phalanx (cf. *R. euryale* and *R. mehelyi*). Tibia 42.1 (39–45)% of FA (n = 31).

Skull delicate; zygomatic arches narrow; zygomatic width = mastoid width. Nasal swellings relatively low. Frontal depression shallow to very shallow; supraorbital ridges poorly developed (Csorba *et al.* 2003). Sagittal crest usually low. Palatal bridge 32–35% of C–M³. Upper incisors weakly bilobed. Upper canine with weak anterior and posterior cusps. Anterior upper premolar small (but moderate to relatively large for a rhinolophid), within tooththrow; canine and posterior premolar well separated. Molar width more than half width of palate between molars (cf. *R. landeri*). Middle lower premolar minute and either within tooththrow or displaced labially, or absent; anterior and posterior lower premolars usually well separated. Crown area of anterior lower premolar equal to or only slightly less than that of posterior lower premolar. Dental formula $^{1123}/_{2133} = 32$ or $^{1123}/_{2123} = 30$.

Geographic Variation Koopman (1994) recognizes three subspecies in Africa.

R. b. blasii: NW Africa (and extraliminally southern Europe and SW Asia).

R. b. andreinii: Ethiopia and Somalia.

R. b. empusa: S DR Congo to the former Transvaal.

Similar Species Only one other *Rhinolophus* in Africa has a connecting process which rises to a high narrow pointed horn:

Rhinolophus euryale. Sella parallel-sided, horseshoe usually narrower (6.5–7.5 mm). First phalanx of fourth finger relatively short (17–22% of fourth metacarpal). Marked contrast between crown areas of anterior and posterior lower premolars. NW Africa.

Two potentially sympatric species (with anterior upper premolar within tooththrow) have triangular connecting processes, which, although lower, also rise to a point:

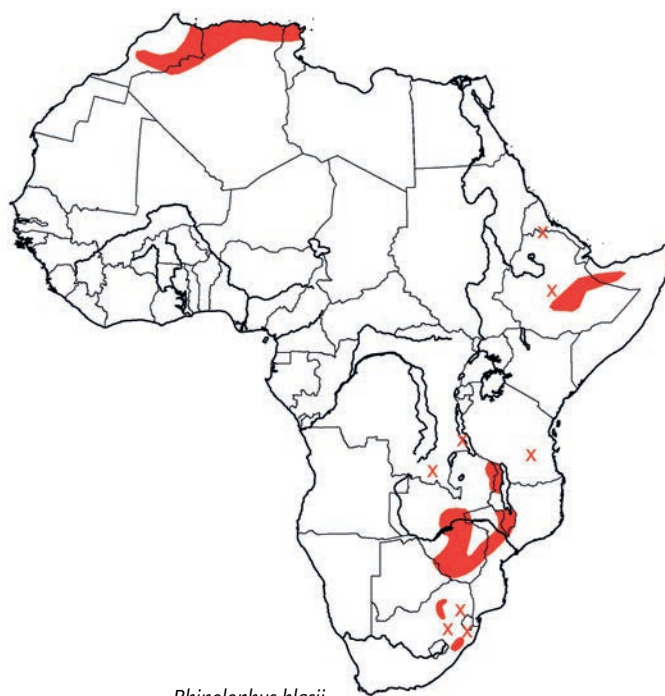

- R. mehelyi*. Usually larger (FA: 48–53 mm). Sella parallel-sided; horseshoe usually narrower (4.9–7.5 mm). First phalanx of fourth finger relatively short (19–23% of metacarpal). Marked contrast between crown areas of anterior and posterior premolars. N Africa.
- R. landeri*. Horseshoe narrower (6.0–8.0 mm). First phalanx of fourth finger relatively short (19–23% of metacarpal). Axillary tufts present in ♂♂. South of Sahara.

Distribution In Africa, occurs in three isolated regions, each occupied by a different subspecies. In NW Africa, found in the Mediterranean Coastal BZ (and marginally in the Sahara Arid BZ). In Ethiopia and Somalia, found in the Afroalpine–Afroalpine BZ (and marginally in the Somalia–Masai Bushland BZ). In south-central and southern Africa, found in the Zambezian Woodland, Afroalpine–Afroalpine and Coastal Forest Mosaic BZs. Two specimens in BMNH, recorded from ‘Cape of Good Hope’, probably came from Mozambique or KwaZulu–Natal (Roberts 1951). Extraliminally: Southern Europe and SW Asia. Mapped from country checklists (see order Chiroptera), other literature and museum records.

Habitat In NW Africa, recorded from Mediterranean sclerophyllous forests, sub-Mediterranean semi-desert grassland and shrubland, and in stone or gravel desert habitats with wadis (but perhaps only where water is available). In Algeria, most localities are near caves and/or streams (Kowalski & Rzebiak-Kowalska 1991). In Ethiopia and Somalia, most localities are in montane vegetation, evergreen and semi-evergreen bushland and thicket, and *Acacia–Commiphora* bushland and thicket. In Malawi and Zambia, found between 500–2300 m, in miombo woodland and montane forests (Ansell 1978, Happold *et al.* 1987). In KwaZulu–Natal, South Africa, most records are from major river valleys in Lowveld, Valley Bushveld and Mistbelt bioregions (Taylor, P. 1998).

Abundance Uncertain. Appears common at least in some parts of geographic range (e.g. very commonly recorded in Malawi; Happold & Happold 1997).

Adaptations Aspect ratio low; wing-loading low; wing-tip rounded (M. Happold unpubl.). Sometimes flies slowly with shallow wing-beats and some gliding and dipping, but can also put on bursts of fast flying with sudden turns. Can take off from ground, hover briefly; flies with great manoeuvrability; turns by banking (minimum radius <25 cm) and by stalling-and-twisting; individuals sustained flight within a 1 × 1 × 1 m enclosure for up to 13 circuits/flight (9 bats, 10 flights each; M. Happold unpubl.). By day, sometimes hangs freely in caves, mine-adits and in cave-like spaces under piles of boulders (Aellen 1955, Smithers 1983), but not found in caves at Zomba, Malawi (Happold *et al.* 1987) and rarely encountered in caves in Algeria (Kowalski *et al.* 1986). Possibly, caves are not utilized except during winter in temperate regions (?). In Algeria, there are some winter records, some individuals being active, others torpid (Kowalski *et al.* 1986). At ambient temperatures of 21–24 °C in Malawi, becomes torpid during the day. Hibernates in caves during winter in the former Transvaal, South Africa (Taylor, P. 1998) and Iran (Lay 1967). Individuals kept in the room of a house and fed winged termites drank ca. five times/night, either by landing and lapping or sucking water from a dish, or by scooping mouthfuls from a tray of water while in flight; predicted mean maximum urine

Rhinolophus blasii

concentration is comparatively low (3116 mOsmol/kg) (Happold & Happold 1988). Undoubtedly very dependent on water in the wild.

Foraging and Food Forages by slow-hawking, fly-catching and both foliage- and ground-gleaning. In Malawi, often forages along hedges and banks of vegetation at the edges of patches of forest, along pathways through dense vegetation, under tree-canopies in relatively uncluttered spaces and within canopies in dense clutter, close to buildings and sometimes over grassy clearings. Foraging is often within 1–2 m of the ground, but can be at least as high as ca. 6 m (M. Happold pers. obs.). In Zambia, analysis of stomach contents indicated that the dry season diet was 100% moths and the wet season diet was 96.5% moths with some termites, flies, beetles and other insects (Whitaker & Black 1976).

Echolocation Call-shape FM/CF/FM; CF-frequency (Malawi) 91–95 kHz, but usually 92–93 kHz (16 ♂♂ and 9 ♀♀ hand-held, 2 ♂♂ flying in open; M. Happold unpubl.). There was no significant difference between the CF-frequencies of ♂♂ and ♀♀. In Swaziland, CF-frequency 85.9 kHz (1 bat; Monadjem 2005). In Europe, mean CF-frequency 94 kHz (Heller & von Helversen 1989).

Social and Reproductive Behaviour Very little is known. In southern Africa, roosts singly or in small groups, never more than three or four together, with individuals hanging apart (Roberts 1951, Rautenbach 1979). In Malawi, often forages in groups of ca. five. Group composition variable; no evidence of harem-formation from these data. In caves in Arabia and the Middle East, has been found roosting singly, in pairs and once in a group of ca. 30 (Harrison & Bates 1991). In Iran, several colonies of 100–500 individuals have been found hibernating in caves (Lay 1967).

Reproduction and Population Structure Litter-size: one. At 15° 23' S (Zomba, Malawi), the reproductive chronology is extended

seasonal monoestry with births in wet season (Nov–Jan) (Happold & Happold 1990a). Extraliminally, in Pakistan, the chronology is restricted seasonal monoestry (Roberts 1977).

Predators, Parasites and Diseases Ectoparasites include a bed-bug *Adroctenes horthvathi* (Hemiptera: Polyctenidae) (Kock *et al.* 1998b); a flea *Rhinolophopsylla unipectinata* (Siphonaptera: Ischnopsyllidae); bat-flies *Phthiridium integrum*, *P. ovale* (Diptera: Nycteribiidae), *Brachytarsina africana*, *Raymondia alulata*, *R. hardyi* (Diptera: Streblidae); mites *Neomyobia africanoides* (Acari: Myobiidae), *Nycteridocoptes eyndhoveni* (Acari: Sarcoptidae) (Anciaux de Faveaux 1984, Beaucournu & Kowalski 1985).

Conservation IUCN Category: Least Concern.

This assessment is based on the global population, which is large, and populations in some areas are stable although others are declining.

Rhinolophus capensis CAPE HORSESHOE BAT

Fr. Rhinolophe du Cap; Ger. Kap-Hufeisennase

Rhinolophus capensis Lichtenstein, 1823. Verz. Doblet. Mus. Univ. Berlin, p. 4. Cape of Good Hope, Cape Province, South Africa.

Taxonomy Species-group: *capensis*. Synonyms: *auritus*. Chromosome number (South Africa): 2n = 58; aFN = 60 (Rautenbach 1986).

Description A small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar usually slightly displaced labially, canine and posterior premolar never in contact; connecting process rounded and higher than sella; lancet hastate; sella with parallel or slightly concave sides; no axillary tufts. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 8–9 mm. Dorsal pelage (grey-phase) pale to medium brown; hairs pale grey, beige or cream, with brown tip. Ventral pelage paler, sometimes more greyish. In orange-phase, dorsal pelage orange-red. No axillary tufts on adult ♂♂. Ears comparatively short (21–25 mm) but of medium relative length (50 [46–52]% of FA). Noseleaf with lancet hastate; tip bluntly pointed. Sella naked, sides parallel or slightly concave; top rounded. Connecting process rounded, sometimes almost triangular but with the top rounded; higher than the sella. Horseshoe narrow (7.3–8.1 mm), not covering whole muzzle; lateral leaflets present but rudimentary; anterior emargination deep. Lower lip with one well-defined groove. Wings and interfemoral membrane brown. First phalanx of fourth finger relatively long (26.4 [24–30]% of fourth metacarpal, n = 29). Mean tibia 41% of mean FA.

Skull robust; zygomatic arches broad; zygomatic width greater than mastoid width. Nasal swellings of medium relative height. Frontal depression shallow; supraorbital ridges weak. Sagittal crest well developed anteriorly, absent posteriorly. Palatal bridge 33–39% of C–M³ (Csorba *et al.* 2003). Interpterygoid groove distinct. Anterior upper premolar small to medium-sized, usually slightly

displaced labially but sometimes almost fully displaced; canine and posterior premolar never in contact, typically well separated (Csorba *et al.* 2003). Middle lower premolar small, partly or fully displaced labially. Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation None recorded.

Similar Species Five other *Rhinolophus* in Africa (those in *capensis* group) have the anterior upper premolar within toothrow and the connecting process rounded, but only three occur in southern Africa (Table 14, p. 304):

Rhinolophus simulator. Connecting process not higher than sella. Body measurements smaller on average (FA: 45.2 [43–47] mm). Skull smaller (CrnC: 17.4–19.4 mm; C–M³: 6.1–6.9 mm). Frontal depression moderately deep; supraorbital ridges prominent. Not known from Eastern and Western Cape Provinces of South Africa.

R. swinnyi. Connecting process not higher than sella. Smaller (FA: 40–45 mm). Skull smaller (CrnC: 17.4–18.0 mm; C–M³: 6.1–6.6 mm).

R. denti denti. Lancet subtriangular. Smaller (FA: 37–44 mm; Tib: 15–18 mm). Skull shorter (CrnC: 15.8–17.0 mm). Semi-arid savannas and deserts.

Because the anterior upper premolar is sometimes displaced labially in *R. capensis*, this species can also be confused with:

R. clivosus. Upper canine and posterior premolar in contact; anterior upper premolar, if present, is small or minute and invariably fully displaced labially. Dorsal pelage darker. Nasal swellings relatively

low. In South Africa, FA, on average, longer (53.6 [49–57] mm, $n = 105$).

Distribution Endemic to Africa. Apparently restricted to a coastal belt (100–200 km wide), mainly in the South-West Cape BZ but extending marginally into the Karoo, Highveld, Coastal Forest Mosaic and Afromontane–Afroalpine BZs, in the Western and Eastern Cape Provinces of South Africa. Herselman & Norton (1985) and Smithers (1983) show the distribution extending along the west coast of South Africa as far north as the Orange R. but, because they found it difficult to distinguish *R. capensis* from *R. darlingi* and *R. clivosus*, records of *R. capensis* north of 32° S, where *R. capensis* might be replaced by *R. darlingi* or *R. clivosus*, need confirmation and have not been mapped here. Records from Zambia and Malawi are erroneous (Koopman 1993); records from Zimbabwe (Hayman & Hill 1971) and one from the NE Eastern Cape Province of South Africa (Lynch 1989) are probably erroneous (Smithers 1983, R. T. F. Bernard pers. obs.).

Habitat Savanna, Afromontane Forest, Coastal Forest and South-West Cape fynbos.

Abundance Common throughout geographic range.

Adaptations Not much known. By day, hangs freely or in contact from the ceilings and walls of caves and disused mine tunnels, but apparently avoids houses. Often shares caves with *R. clivosus*: the two species sometimes hang in separate clusters (Herselman & Norton 1985) and sometimes in clusters comprised of ♂♂ and ♀♀ of both species (McDonald *et al.* 1990b). Sometimes also shares caves with *Miniopterus natalensis*. Sometimes hibernates in winter, but torpor not as deep as in *R. clivosus* (R. T. F. Bernard pers. obs.). Small-scale migrations of 10 km have been noted (Taylor 2000).

Foraging and Food On basis of wing morphology, predicted to forage by flying slowly through vegetation and gleaning from the ground or foliage (McDonald *et al.* 1990a). The number of individuals emerging from a cave, and activity outside the cave (both assessed from the number of captures/minute in a harp-trap set at the entrance), was found to be maximal during the first two hours after sunset; this presumably indicates that foraging activity is greatest during this time although some of the measured activity was probably associated with bats returning to the cave to roost in between bouts of foraging (McDonald *et al.* 1990a). At Algeria Forest station, Western Cape, individuals were seen regularly using the eaves of buildings at night, and culled parts of insects and faeces found in the morning suggests they used the eaves as night roosts (Seamark 2005). Diet is mainly beetles (McDonald *et al.* 1990a, Taylor 2000).

Echolocation Call-shape FM/CF/FM. CF-frequency 85–90 kHz (McDonald *et al.* 1990a).

Social and Reproductive Behaviour Roosts in colonies, which seldom contain more than 500 (R. T. F. Bernard pers. obs.) but sometimes contain more than a thousand individuals (Herselman & Norton 1985). Both sexes roost together. Individuals roost in clusters, but tend not to be in contact with each other.

Rhinolophus capensis

Reproduction and Population Structure Litter-size: one ($n = 27$). At 33–34° S in South Africa, the reproductive chronology is restricted seasonal monoestry, with spermatogenesis between Oct–May; sperm storage in the cauda epididymides throughout winter (which is unusual for a rhinolophid); copulation at end of winter (Aug–Sep); and births in summer (Nov–Dec) after 3–4 month gestation (Bernard 1985, 1988). Although ♀♀ are in oestrus or submaximal oestrus in May, cornified epithelial cells block the vagina and prevent copulation throughout the winter hibernation period. In contrast, most hibernating species of *Rhinolophus* copulate before hibernating and ♀♀ store the sperm until they ovulate in the spring. Females do not become reproductively active in their first year. Testes of ♂♂ are active after 11–12 months, but first matings occur in the second year.

Predators, Parasites and Diseases Ectoparasites include fleas *Rhinolophopsylla ashworthi*, *R. capensis* (Siphonaptera: Ischnopsyllidae); bat-flies *Nycteribia schmidli*, *Phthiridium scissum* (Diptera: Nycteribiidae), *Brachytarsina africana* (Diptera: Streblidae), mites *Neomyobia jacksoni*, *N. africanoides* (Acari: Myobiidae), *Labidocarpus rollinatti*, *Alabidocarpus diceratops* (Acari: Chirodiscidae), *Opsonyssus zumpti* (Acari: Gastronyssidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

The extent of occurrence is >20,000 km², but it is known from only ca. 15 locations and there is a decline in the extent and quality of habitat.

Rhinolophus clivosus GEOFFROY'S HORSESHOE BAT (CRETZSCHMAR'S HORSESHOE BAT)

Fr. Rhinolophe de Cretzschmar; Ger. Geoffroys Hufeisennase

Rhinolophus clivosus Cretzschmar, 1828. In: Rüppell, Atlas Reise Nordl. Afr., Säugeth., p. 47. Mohila, Saudi Arabia.

Taxonomy Species-group: *ferrumequinum*. Synonyms: *acrotis* Heuglin, 1861, *andersoni*, *augur*, *brachygnathus*, *keniensis*, *schwarzi*, *zambesiensis*, *zuluensis*. Subspecies: seven, six in Africa. Variability in measurements, bacular morphology, colour, habitat, echolocation calls and reproduction strongly suggest *R. clivosus* includes more than one species. Chromosome number (East Africa): 2n = 58; aFN = 62 (Dulić & Mutere 1974). In South Africa, 2n = 58; aFN = 60 or 62 and X and Y are large submetacentrics (Rautenbach 1986).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar displaced labially or absent; upper canine and posterior premolar always in contact; connecting process rounded and high; sella naked with concave sides; horseshoe breadth 6.6–9.6 mm; nasal swellings very low; no axillary tufts. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs ca. 8 mm. Dorsal pelage variable: cream, grey, brownish-grey, greyish-fawn or reddish-brown; hairs pale, usually with darker-coloured tip. Ventral pelage beige, pale brown or grey. Individuals in orange-phase have been recorded. No axillary tufts on adult ♂♂. Ears comparatively and relatively short (16–24 mm, 39 [30–47]% of FA). Noseleaf with lancet hastate; tip rounded. Connecting process rounded but sometimes smoothly curved and sometimes slightly angular; slightly to clearly higher than sella. Sella naked, narrow, with concave sides; top broad and rounded (Figure 60d). Horseshoe narrow–medium (6.6–9.6 mm depending on subspecies), not covering whole muzzle; lateral leaflets present but sometimes rudimentary; median emargination is a shallow to moderately deep notch. Lower lip with a well-defined median groove; lateral grooves distinct, indistinct or absent. Wings and interfemoral membrane dark grey. First phalanx of fourth finger relatively long (28.4 [25–31]% of fourth metacarpal, n = 50). Tibia 42.1 (33–49)% of FA, n = 64. Baculum: basal cone with shallow dorsal invagination and deep ventral invagination; shaft dorsoventrally flattened without expanded tip in *R. c. zuluensis*, but with slightly expanded tip in *R. c. augur*, length 4.7 (4.5–5.2) mm, n = 3 in *R. c. augur*, 3.6 (3.2–4.0) mm, n = 21 in *R. c. zuluensis* (based on Cotterill 2002a). No data for other subspecies.

Skull robust; zygomatic width greater than mastoid width. Nasal swellings relatively low. Frontal depression very shallow; supraorbital ridges weak. Sagittal crest low anteriorly, absent posteriorly. Palatal bridge relatively short (25–31% of C–M³; Csorba *et al.* 2003). Interpterygoid groove absent or very indistinct. Anterior upper

premolar minute and fully displaced labially, or absent; upper canine and posterior in contact. Middle lower premolar minute and fully displaced labially, or absent; anterior and posterior lower premolars in contact. Dental formula $^{1123}/_{2133} = 32$, $^{1113}/_{2133} = 30$, $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$.

Geographic Variation Seven subspecies are currently recognized (Thomas 1997, Csorba *et al.* 2003) of which six are represented in Africa:

R. c. schwarzi: SE Algeria and SW Libya.

R. c. brachygnathus: NE Libya, Egypt, N Sudan (and extraliminally Israel).

R. c. acrotis: most of C and S Sudan, and Ethiopia. Comparatively small.

R. c. keniensis: SE Sudan, Uganda, Kenya and N Tanzania. Intermediate in size.

R. c. augur: S Tanzania, Malawi, Zimbabwe, Botswana and N South Africa. Largest.

R. c. zuluensis: coastal South Africa. Intermediate in size.

The bacular morphologies of *R. c. augur* and *R. c. zuluensis* are very different (Cotterill 2002a, F. P. D. Cotterill unpubl.).

Similar Species Six other *Rhinolophus* in Africa have the following combination of characters – anterior upper premolar fully displaced labially or absent; connecting process rounded; sella naked (or with sparse short hairs only) (Table 14, p. 304):

Rhinolophus darlingi. FA often shorter (47 [42–51] mm). Dorsal pelage greyer. Nasal swellings of medium relative height. Interpterygoid groove distinct. Palatal bridge relatively longer (30–35% of C–M³).

R. silvestris. Lancet subtriangular. Horseshoe broader (9.5, 10.3 mm), as broad as muzzle. Connecting process lower. Nasal swellings of medium relative height. Frontal depression moderately deep; supraorbital ridges prominent. Interpterygoid groove shallow but distinct. Rainforest BZ; Gabon and Congo.

R. deckenii. Lancet subtriangular. Horseshoe broader (9.1–11.5 mm), as broad as muzzle. Connecting process lower (ca. same height as sella). Nasal swellings of medium relative height. Frontal depression moderately deep; supraorbital ridges prominent.

Interpterygoid groove shallow but distinct. Upper canine and posterior premolar usually separated by narrow gap. East Africa. Furthermore, the tibia is longer (24–28 mm), the horseshoe is broader and the skull is longer (CrnC: 22.6–24.1 mm) than in sympatric *R. c. keniensis*.

R. sakejensis. Connecting process rising to high, rounded peak, much higher than sella. Horseshoe breadth 10.3 mm, $n = 1$. Skull larger (CrnC: 24.3–25.3 mm; C–M³: 9.4–9.7 mm).

R. hillorum. Connecting process higher and narrower in profile. Skull larger and more robust (CrnC: 23.3–24.4 mm; C–M³: 8.9–9.5 mm). Anterior upper premolar absent. Rainforest BZ from Guinea and Liberia to Cameroon, and possibly, S Sudan.

R. ferrumequinum. Forearm, on average, longer (55.4 [51–59] mm). As yet, African records are only in the Maghreb (NW Africa).

Distribution In Africa, mainly recorded from the Sahara Arid, Somalia–Masai Bushland, Zambezian Woodland, South-West Arid, Highveld, South-West Cape and Afromontane–Afroalpine BZs, with some records in the Eastern and Southern Rainforest–Savanna Mosaics and the Coastal Forest Mosaic BZ. Not recorded from the Rainforest BZ. Distributed, apparently very disjunctly, from Algeria to Egypt and southwards through most countries on the eastern side of Africa to South Africa. Also recorded from W Namibia and S Angola, and at an isolated locality in SW DR Congo. Not recorded from Tanzania (where previous records are now considered to represent *R. deckenii* and *R. fumigatus* (F. P. D. Cotterill pers. comm.)). Records from Kitale, Kenya (HZM, USNM) also possibly represent *R. deckenii*. Extralimittally: Israel, Jordan and Arabian Peninsula (Simmons 2005). Mapped from country checklists (see order Chiroptera), other literature and museum records.

Habitat Woodland savannas, montane forests, open grasslands, semi-desert and desert habitats. In Algeria, probably restricted to mountains in the Sahara Desert region (Kowalski & Rzebik-Kowalska 1991). In NE Africa, occurs in sub-desert and savanna habitats (Qumsiyeh 1985). Mainly associated with mountainous and hilly areas in Sudan and Kenya (Koopman 1975), Zambia (Ansell 1978), Zimbabwe (Hutton 1986) and also in Rwanda and DR Congo. In Malawi, recorded from montane forest, miombo woodland and thicket-clump savanna, from 100 to 2300 m (Happold *et al.* 1987). In southern Africa, occurs mainly in woodland savannas, but extends into deserts in the west, and grasslands in the Drakensberg Mts (Taylor 2000). Throughout geographic range, its occurrence probably depends on availability of caves and/or cave-like day-roosts.

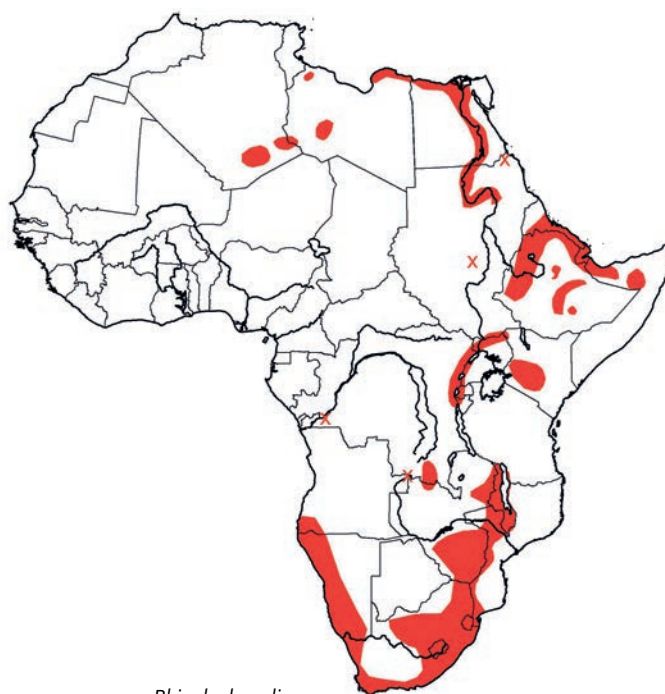

Abundance Uncertain throughout most of geographic range. Reported ‘rarely recorded’ in Malawi (Happold & Happold 1997), common in southern Africa (Taylor 2000), and locally abundant in vicinity of caves in Rwanda (Baeten *et al.* 1984) and South Africa (Herselman & Norton 1985).

Adaptations Aspect ratio low; wing-loading very low; wing-tip rounded (M. Happold unpubl.). Flight very variable in speed and highly manoeuvrable. Can take off from ground and almost hover. Turns by banking (minimum radius <25 cm), and by stalling-and-twisting; individuals sustained flight within a 1 × 1 × 1 m enclosure for up to eight circuits/flight (4 bats, 10 flights each; M. Happold unpubl.).

By day, hangs freely from ceilings or in contact with walls, in caves, rock crevices, abandoned mine tunnels, catacombs, stone huts and other cave-like places in abandoned buildings. Also roosts in hollow baobabs *Adansonia*. Inter-cave movements of up to 10 km (Herselman 1980, Rautenbach 1982, McDonald *et al.* 1990b), and prolonged periods of hibernation (R. T. F. Bernard unpubl.), occur in South Africa. In Malawi, at ambient temperatures of 21–24 °C, becomes torpid during day (Happold & Happold 1988). Considered more arid-adapted than *R. ferrumequinum* (Harrison & Bates 1991; Thomas 1997). Captive individuals, feeding on winged termites, drank regularly. Predicted mean maximum urine concentration is comparatively low (2981 mOsmol/kg); therefore probably very dependent on water for drinking in the wild (Happold & Happold 1988).

Foraging and Food In Malawi and southern Africa, forages under canopies of trees and along banks of vegetation, in areas of moderate clutter. Foraging begins ca. half an hour after sunset (Smithers 1983). Forages by slow-hawking and fly-catching, and predictably by gleaning. Individuals eat while hanging from branches, and sometimes from perches in verandas, and these perches are marked by accumulations of discarded fragments of insects. In South Africa, fragments under perches included moths and small beetles (Rautenbach 1979). In Zimbabwe, faecal pellets of two individuals contained only beetles (Fenton *et al.* 1977). Captive bats ate mantises (Dictyoptera: *Miomantis* sp.) that were thrown into the air near perching bats; the bats responded by taking flight and capturing the prey in mid-air (as in typical fly-catching) (Cumming 1996). The mantises responded to the echolocation calls of approaching bats by swerving and diving sharply to the ground; deafened mantises did not respond in this way.

Echolocation Call-shape FM/CF/FM. CF-frequency (Malawi) 79–84 kHz (usually 82–84 kHz) (M. Happold unpubl.). In South Africa, 90–100 kHz (McDonald *et al.* 1990a), 80–85 kHz (Cumming

Rhinolophus clivus

1996); 94 kHz (Taylor 1999a). In Swaziland, 90.9 kHz (1 bat; Monadjem 2005). This variation in CF-frequency strongly suggests that the South African and Swaziland bats represent two different species, one of which also occurs in Malawi.

Social and Reproductive Behaviour In Algeria, roosts singly or in groups of up to 50 individuals (Kowalski & Rzebik-Kowalska 1991). In Malawi and southern Africa, roosts singly, in small groups (M. Happold unpubl., R. T. F. Bernard unpubl.) and in colonies of up to 10,000 individuals (Herselman & Norton 1985). Bats roosting in a small group hang slightly apart within a cluster. In very large colonies, there are many small clusters. Roosts usually contain individuals of both sexes, even when young and subadults are present.

Reproduction and Population Structure Litter-size: one. In Zimbabwe, the reproductive chronology is restricted seasonal monoestry with copulation in the dry season (Jun–Jul) and parturition at the beginning of the unimodal wet season (mid-Nov) (R. T. F. Bernard & F. P. D. Cotterill unpubl.). At ca. 29° S (KwaZulu–Natal, South Africa), the reproductive chronology is also restricted seasonal monoestry with copulation in autumn (Apr), sperm-storage by the ♀♀ until late winter (Aug) when ovulation and fertilization occur, and parturition in summer (Nov–Dec) (Bernard 1983, 1988). Gestation 3.5 months; lactation approximately 2 months. In contrast, at ca. 25° S (Gauteng Highveld, South Africa), ♀♀ do not uniformly store spermatozoa for prolonged periods and sperm-storage seems to take place in the ♂♂ (Wessels & van der Merwe 1997). The differences in reproduction lend weight to the probability that *R. clivosus* contains more than one species. Approximately 20% of ♀♀ are sexually mature after 18 months, 80% after 18 months and the remainder after 42 months or more (Wingate 1986).

Predators, Parasites and Diseases Ectoparasites include fleas *Xenopsylla nubica* (Siphonaptera: Pulicidae), *Oxyparius isomalus*,

Rhinolophopsylla ashworthi, *R. capensis* (Siphonaptera: Ischnopsyllidae); 13 species of bat-flies (Diptera: Nycteribiidae, Streblidae); four species of ticks (Acari: Argasidae, Ixodidae); 14 species of mites (Acari: Amblyomidae, Spinturnicidae, Macronyssidae, Myobiidae, Trombiculidae, Psorergatidae, Chirodiscidae, Sarcoptidae and Gastronyssidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

On the Zimbabwe plateau (>1000 m) its occurrence has been augmented by the increased density of abandoned mines.

Rhinolophus darlingi DARLING'S HORSESHOE BAT

Fr. Rhinolophe de Darling; Ger. Darlings Hufeisennase

Rhinolophus darlingi K. Andersen, 1905. Ann. Mag. Nat. Hist., ser. 7, 15: 70. Upper Mazoe Valley, Mashonaland, Zimbabwe.

Taxonomy Species-group: *ferrumequinum*. Synonyms: *barbertonensis*, *damarensis*. Subspecies: two. The taxonomic status of a population in Nigeria is unclear (Hill *et al.* 1988; Csorba *et al.* 2003). Chromosome number (South Africa): 2n = 58; aFN = 60. X = large subtelocentric, Y = small metacentric (Rautenbach 1986).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar displaced labially or absent; connecting process rounded; lancet subtriangular; sella with concave sides; no axillary tufts. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 8–10 mm. Dorsal pelage grey, brownish-grey or greyish-brown; hairs cream or pale greyish-brown with grey, brownish-grey or greyish-brown tip. Ventral pelage paler, often pale grey. Apparently no orange-phase. No axillary tufts on adult ♂♂. Ears comparatively and relatively short (15–23 mm, 42 [40–47]% of FA).

Noseleaf with lancet large, subtriangular, sides slightly concave: tip bluntly pointed. Connecting process smoothly rounded, ca. same height as sella or slightly lower. Sella naked, sides concave, top broad and rounded. Horseshoe narrow (7.1–8.7 mm) but almost covering muzzle; lateral leaflets present; median emargination deep. Lower lip with one groove. Wings and interfemoral membrane translucent grey to black. First phalanx of fourth finger relatively long (27.3 [24–30]% of fourth metacarpal, n = 52). Tibia 42.0 (41–47)% of FA, n = 17. Baculum trumpet-shaped with round, relatively short shaft (total length <2 mm).

Skull robust; zygomatic arches sturdy; zygomatic width greater than mastoid width. Nasal swellings of medium relative height. Frontal depression shallow to moderately deep; supraorbital ridges pronounced. Sagittal crest moderately well developed anteriorly, weak to absent posteriorly. Palatal bridge of medium relative length 30–35% of C–M³ (Csorba *et al.* 2003). Interpterygoid groove well

defined. Anterior upper premolar small and fully displaced labially, or absent; canine and posterior premolar in contact. Middle lower premolar minute and fully displaced labially, or absent; anterior and posterior lower premolar in contact. Dental formula $^{1123}/_{2133} = 32$, $^{1113}/_{2133} = 30$, $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$.

Geographical Variation Two subspecies are recognized by Meester *et al.* (1986) and Koopman (1994):

R. d. darlingi: Angola, Tanzania, Malawi, Mozambique, Zimbabwe, E and N Botswana, NE South Africa.

R. d. damarensis: Namibia and South-West Arid Zone in neighbouring countries.

Measurements of specimens from Nigeria (Hill *et al.* 1988) fall almost entirely within the range of *R. d. darlingi*, but more material is needed to establish the subspecific status of the West African population (Csorba *et al.* 2003). Furthermore, the true pattern of variation of *R. darlingi* in Tanzania, Malawi and Mozambique is unclear.

Similar Species Four other African *Rhinolophus* occurring south of the Equator have the following combination of characters – anterior upper premolar fully displaced labially or absent; connecting process rounded; sella naked (or with sparse short hairs only) (Table 14, p. 304):

Rhinolophus clivosus. FA often longer (51.5 [42–59] mm). Dorsal pelage browner. Nasal swellings low. Interpterygoid groove absent or indistinct. Palatal bridge relatively shorter (25–31% of C–M³).

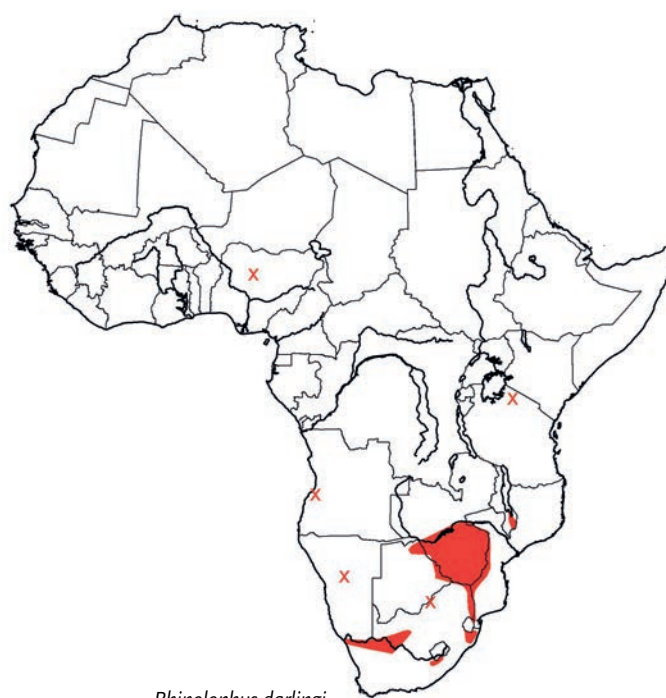

R. deckenii. Horseshoe broader (9.1–11.5 mm). FA usually longer (53 [48–56] mm). Skull larger (CrnC: 22.6–24.1 mm; C–M³: 8.2–9.4 mm).

R. sakejensis. Larger (FA: 53–55 mm; CrnC: 24.3–25.3 mm). All three known specimens are in orange-phase. Horseshoe broader (10.3 mm). Nasal swellings low. Frontal depression extremely shallow; supraorbital ridges indistinct. Anterior upper premolar absent in the three known specimens; canine and posterior premolar in contact.

R. silvestris. Horseshoe broader (9.5, 10 mm). FA longer (50–56 mm). Skull larger (CrnC: 22.3–23.7 mm; C–M³: 8.7–9.3 mm).

Distribution Endemic to Africa. Mainly recorded from parts of the Zambezian Woodland, Highveld, South-West Arid, Afromontane–Afroalpine and Coastal Forest Mosaic BZs in south-central Africa and southern Africa, with outlying records in the Guinea Savanna BZ in West Africa, and in the Afromontane–Afroalpine BZ in Tanzania. Recorded very disjunctly from Nigeria and N Tanzania, and from Angola to Malawi and southwards to South Africa. Occurs throughout Zimbabwe (F. P. D. Cotterill unpubl.); records in other countries are scarce and scattered (Andersen 1905a, Smithers & Lobão Tello 1976, Smithers 1983, Hill *et al.* 1988, Taylor 2000, Csorba *et al.* 2003 and others).

Habitat Mesic and semi-arid woodland savannas where suitable day-roosts (including caves and abandoned mines) are present. In southern part of its geographic range, particularly associated with broken, rocky terrain (Smithers 1983). Absent from deserts.

Rhinolophus darlingi

Abundance Rarely recorded in Malawi (Happold & Happold 1997), and apparently rare elsewhere north of the Zambezi R. Locally common in vicinity of day-roosts in Zimbabwe, Namibia and South Africa.

Adaptations Aspect ratio low; wing-loading very low (F. P. D. Cotterill unpubl.). Flight predicted to be slow and very manoeuvrable. Day-roosts include caves, abandoned mine-adits, cavities and fissures in rock or in piles of boulders, large hollow trees, disused buildings (including under the floors of disused houses in Kruger N. P. [Pienaar *et al.* 1980]); hangs freely from ceilings (Rautenbach 1982, Smithers 1983). Complete darkness not essential: at least some roosts are dimly lit. In Namibia, three caves used as day-roosts varied greatly in humidity but the temperature remained almost constant (24–24.5 °C) (Churchill *et al.* 1997). In Zimbabwe, *R. darlingi* enters torpor daily during the cool-dry season (F. P. D. Cotterill unpubl.).

Food and Foraging No information. Based on wing morphology and echolocation, predicted to forage in cluttered habitats (Aldridge & Rautenbach 1987). Diet not known.

Echolocation Call-shape FM/CF/FM. CF-frequency (Swaziland) 86 kHz; maximum duration 35.2 ms (10 bats; Taylor 1999a).

Social and Reproductive Behaviour Usually roosts in groups of 'dozens of individuals' (Smithers 1983); a group of ca. 20 individuals is reported from KwaZulu–Natal (South Africa) by Taylor, P. (1998), and one of ca. 160 individuals from Namibia by Churchill *et al.* (1997). In the former Transvaal (South Africa), groups of 2–15 were recorded by Rautenbach (1982). Group members hang in clusters but with each individual slightly separated from its neighbours.

Reproduction Litter-size: normally one; twinned foetuses near full term, one in each uterine horn, were observed once in

Zimbabwe (Smithers & Wilson 1979). Reproductive chronology uncertain. In Zimbabwe, ♀♀ with young were recorded in Oct, and one pregnant ♀ in Dec (Smithers & Wilson 1979). No pregnant or lactating ♀♀ have been found during the cool-dry season (F. P. D. Cotterill unpubl.). In the former Transvaal (South Africa) one pregnant ♀ was recorded in Oct (Rautenbach 1982). The data are consistent with monoestry, but this needs confirmation.

Predators, Parasites and Diseases Ectoparasites include a flea *Echidnophaga aethiops* (Pulicidae); bat-flies *Phthiridium scissum*, *P. tectum* (Diptera: Nycteribiidae) and *Brachytarsina africana* (Diptera: Streblidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Rhinolophus deckenii DECKEN'S HORSESHOE BAT

Fr. Rhinolophe de Decken; Ger. Deckens Hufeisennase

Rhinolophus deckenii Peters, 1868. Monatsber. K. Preuss. Akad. Wiss. Berlin 1867: 705 (publ. 1868). 'Zanzibar Coast'
[= mainland opposite Zanzibar I.], Tanzania.

Taxonomy Species-group: *ferrumequinum*. Treated as a subspecies of *R. clivosus* by Hayman & Hill (1971), but considered to be a distinct species by Koopman (1975, 1993, 1994) and subsequently by many authors including Csorba *et al.* (2003) and Simmons (2005). Synonyms: currently none. Subspecies: currently none, but some authors, including Aellen (1959) and Csorba *et al.* (2003), suggest that *silvestris* (tentatively treated here as a distinct species) is probably a western subspecies of *R. deckenii*. Chromosome number: no information.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar displaced labially or absent; connecting process rounded; lancet subtriangular; sella with slightly concave sides; no axillary tufts; dorsal pelage greyish-brown, apparently no orange-phase (cf. *R. sakejensis*); baculum with flattened, spatulate shaft (cf. *R. silvestris*). Difficult to distinguish from *R. silvestris* except by distribution and baculum morphology (see Similar Species). Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 8–10 mm. Dorsal pelage medium greyish-brown; hairs greyish-fawn with medium greyish-brown at tip. Ventral pelage slightly paler. Apparently no orange-phase. No axillary tufts on adult ♂♂. Ears comparatively and relatively medium-short (18–27 mm, 39–49% of FA). Noseleaf with lancet high, subtriangular (Figure 61b), sides straight or slightly concave, tip bluntly pointed. Connecting process rounded, ca. same height as sella. Sella naked, sides parallel or slightly concave, top broad and rounded. Horseshoe of medium breadth (9.1–11.5 mm), covering whole muzzle; lateral leaflets present; median emargination distinct. Lower lip with a well-defined median groove and two poorly-defined lateral grooves.

Wings brown, semi-translucent; interfemoral membrane slightly paler and more translucent (museum material). First phalanx of fourth finger relatively long (27.1 [24–30]% of fourth metacarpal, n = 25). Tibia 46.7 (44–50)% of FA, n = 24. Baculum with dorsal and ventral parts of basal cone deeply invaginated so sides of cone form two long wings; shaft spatulate and dorsoventrally flattened; tip not expanded; length 3.8 (3.6–4.2) mm, n = 7 (Cotterill 2002a).

Skull robust; zygomatic arches sturdy; zygomatic width much greater than mastoid width. Nasal swellings of medium relative height, lateral profile smoothly rounded. Frontal depression moderately deep; supraorbital ridges prominent. Sagittal crest well developed anteriorly, absent posteriorly. Palatal bridge 29–34% of C–M³ (Csorba *et al.* 2003). Interpterygoid groove shallow but distinct. Anterior upper premolar minute, fully displaced labially (or rarely only half-way displaced), or absent; upper canine and posterior premolar usually separated by a very narrow gap (Csorba *et al.* 2003). Middle lower premolar absent; anterior and posterior lower premolars in close contact. Anterior lower premolar ≤ half height, and ≤ half of the crown area, of the posterior premolar. Dental formula $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$.

Geographic Variation None currently recognized, but see Taxonomy.

Similar Species Only three other *Rhinolophus* occurring in eastern Africa (or perhaps likely to occur there) have the following combination of characters: anterior upper premolar displaced labially or absent; connecting process rounded; sella naked (or with sparse short hairs only):

Rhinolophus clivosus. Lancet hastate; horseshoe narrower (6.6–9.6 mm), not covering whole muzzle; connecting process higher, lateral profile smoothly curved. Nasal swellings very low. Interpterygoid groove absent or very indistinct. Upper canine and posterior premolar always in contact. Where sympatric, tibia usually shorter (21–24 mm) and skull shorter (CrnC: 19.8–20.9 mm).

R. darlingi. Horseshoe narrower (7.1–8.7 mm). FA usually shorter (47 [42–51] mm). Skull smaller (CrnC: 18.4–20.5 mm, C–M³: 6.7–7.3 mm).

R. hillorum. Horseshoe narrower (8.6, 8.7 mm, n = 2). Skull with nasal swellings low. Frontal depression very shallow, supraorbital ridges indistinct. Anterior upper premolar absent in all known specimens; canine and posterior premolar in contact. Rainforest BZ, Guinea and Liberia to Cameroon (and possibly Sudan).

Rhinolophus silvestris, known only from the Rainforest BZ in Gabon and Congo, is almost indistinguishable morphometrically from *R. deckenii* but has higher nasal swellings and the baculum has a rounded shaft. *Rhinolophus sakejensis*, as yet known only from Zambia, has all three known specimens in orange-phase and the connecting process rises to high rounded peak. *Rhinolophus fumigatus*, *R. eloquens* and *R. hildebrandtii*, which also occur in East Africa and have the anterior upper premolar displaced labially, the connecting process rounded and the horseshoe broader than 10 mm, differ from *R. deckenii* in having hairy sellas (Table 14, p. 304).

Distribution Endemic to Africa. Mainly recorded from the Coastal Forest Mosaic BZ of Kenya, Tanzania, Mafia I. (Kock & Stanley 2009), Pemba I. and Zanzibar I. (Kulzer 1959, Aggundey & Schlitter 1984, Pakenham 1984, Cockle *et al.* 1998, BMNH, HZM), but there are isolated records from the Afromontane–Afroalpine BZ and Zambezi Woodland BZ in inland Tanzania (HZM), and from the Eastern Rainforest–Savanna Mosaic in Uganda (LACM, W. Bogdanowicz pers. comm.). According to Thorn & Kerbis Peterhans (2009), the Ugandan records represent *R. clivosus* or *R. alcyone* (not *R. deckenii*). One specimen was reported from Chinizua Forest, C Mozambique, but without further information (Monadjem *et al.* 2010) (not mapped).

Habitat Mainly known from the small coastal forests that are part of the East African coastal forest mosaic. Bat assemblages in the Tanzanian coastal forests are documented by Cockle *et al.* (1998). The inland records are in drier miombo woodland at 650 m, and in afromontane vegetation on the slopes of Kilimanjaro: no information for Uganda.

Abundance Uncertain. Numerous in at least two Tanzanian coastal forests (Cockle *et al.* 1998).

Remarks Day-roosts on Zanzibar I. include underground caverns and deep caves in coral-rock country, the dark interior of a ruined Marahubi Palace, and within ruined Persian Baths (Pakenham 1984). Also found roosting in an empty mud house on Pemba I. (Pakenham 1984). Collections of bats taken from these day-roosts comprised (a) 2 ♂♂ and 14 ♀♀ of which 11 carried advanced foetuses in Oct, (b) 1 ♂ and 1 ♀ with large foetus in Oct, (c) 2 ♂♂ in Nov, (d) 2 ♂♂ and one non-pregnant ♀ in Mar, (e) 1 ♂ in Jan, (f) 1 ♂ in Jan

and (g) 3 ♂♂ and 5 ♀♀ (of which two had very early embryos) in Aug. However, it is not stated that all occupants of these roosts were captured. Two roosts were shared with *Hipposideros caffer*, and another with *Nycteris macrotis* and *N. thebaica*. Ectoparasites on *R. deckenii* from these two roosts included bat-flies (Diptera: Streblidae), lice and ticks (Pakenham 1984).

Conservation IUCN Category: Near Threatened.

Population probably significantly declining because of deforestation: close to qualifying for Vulnerable. The coastal forests of East Africa are on the verge of eradication because they lie inside a rapidly developing area with high population density (Cockle *et al.* 1998).

Rhinolophus deckenii

Rhinolophus denti DENT'S HORSESHOE BAT

Fr. Rhinolophe de Dent; Ger. Dents Hufeisennase

Rhinolophus denti Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 13: 386. Kuruman, Cape Province, South Africa.

Taxonomy Species-group: *landeri*. Groups phenetically with *swinyi* and *simulator* (Bogdanowicz 1992, Bogdanowicz & Owen 1992). Synonyms: *knorri*. Subspecies: two. Csorba *et al.* (2003) suggest *R. denti* might include *swinyi*. Many literature references to *R. denti*, notably those in Zimbabwe, actually refer to *R. swinyi*. Chromosome number (South Africa): $2n = 58$; $aFN = 62$; $X =$ large subtelocentric, $Y =$ small metacentric (Rautenbach 1986).

Description Small to very small microbat with noseleaf (posterior component subtriangular with erect tip); small for an African rhinolophid; anterior upper premolar within tooththrow; connecting process rounded; lancet subtriangular with slightly convex sides; sella parallel-sided or with slightly concave sides; no axillary tufts; ears 18 (14–21) mm. Sexes similar. Pelage soft; mid-dorsal hairs 6–7 mm. Dorsal pelage (grey-phase) pale brown (buff) to pale grey or cream; hairs nearly unicoloured, or very pale with brown or grey near the tip. Ventral pelage white, off-white or pale grey. In orange-phase, dorsal pelage bright orange, ventral pelage slightly paler. No axillary tufts on adult ♂♂. Ears comparatively and relatively short (14–21 mm, 44 [38–48]% of FA). Noseleaf with lancet relatively short, well covered with fine pelage, subtriangular with sides slightly concave; tip bluntly pointed. Connecting process rounded, ca. same height as sella. Sella naked with sides almost parallel or slightly concave; top broad and rounded. Lobes at base of sella comparatively low (cf. *R. simulator*). Horseshoe narrow (6.8–7.5 mm) but almost covering muzzle; no lateral leaflets; anterior emargination a distinct notch. Lower lip with three grooves. Wings and interfemoral membrane greyish-black or brown. First phalanx of fourth finger of medium relative length (23.9 [21–27]% of fourth metacarpal, $n = 44$). Tibia 40.5 (40–43)% of FA, $n = 17$.

Skull delicate; zygomatic arches thin; zygomatic width equal or slightly greater than mastoid width. Nasal swellings rounded; relative height medium–low. Frontal depression shallow; supraorbital ridges weak. Sagittal crest very low anteriorly, absent posteriorly. Palatal bridge of medium relative length (30–35% of $C-M^3$). Anterior upper premolar small, within tooththrow; canine and posterior premolar well separated. Lower canines distinctly smaller and shorter than upper canines (cf. *R. landeri*). Middle lower premolar minute, fully displaced labially; anterior and posterior lower premolars in contact. Anterior lower premolar (*R. d. denti*) one half the height of the posterior lower premolar (Kock *et al.* 2002). Dental formula $1123/2133 = 32$.

Geographic Variation Two subspecies are recognized (Koopman 1994):

R. d. knorri: West Africa (details below). Body measurements on average smaller (FA: 38–41 mm; E: 14–17 mm; Tib: 15–16 mm) (Rosevear 1965). Skull longer (CrnC: 17.0–17.6 mm) (Rosevear 1965). Darker, ventral pelage pale grey; ears, wings and interfemoral membrane greyish-black.

R. d. denti: southern Africa. Body measurements on average larger (FA: 40–44 mm; E: 18–21 mm; Tib: 17–18 mm) (Smithers 1983). Skull shorter (GLS: 15.8–17.0 mm) (Rautenbach 1986). Paler, ventral pelage white or off-white; ears, wings and interfemoral membrane brown.

Similar Species Five other African *Rhinolophus* have the anterior upper premolar within tooththrow and the connecting process rounded (Table 14, p. 304):

Rhinolophus simulator simulator. Lancet hastate. Often larger (FA: 43–47 mm; E: 21 [18–23] mm; CrnC: 18.5 [17.4–19.4] mm). Lobes at base of sella higher. Skull with frontal depression moderately deep; supraorbital ridges prominent. Rostrum longer and broader. Mesic woodland savannas. In southern Africa, not recorded west of 25° E.

R. swinyi. Lancet hastate. Top of sella broad and rounded. Tibia often longer (17–21 mm). Cranially indistinguishable except CrnC usually longer. Montane forests and woodland savannas. In southern Africa, not recorded west of 24° E.

R. capensis. Lancet hastate. Larger (FA: 47–51 mm). Skull longer (CrnC: 20.0–21.1 mm). Known only from Cape Province of South Africa.

R. adami. Larger (FA: 46–50 mm). Known only from DR Congo.

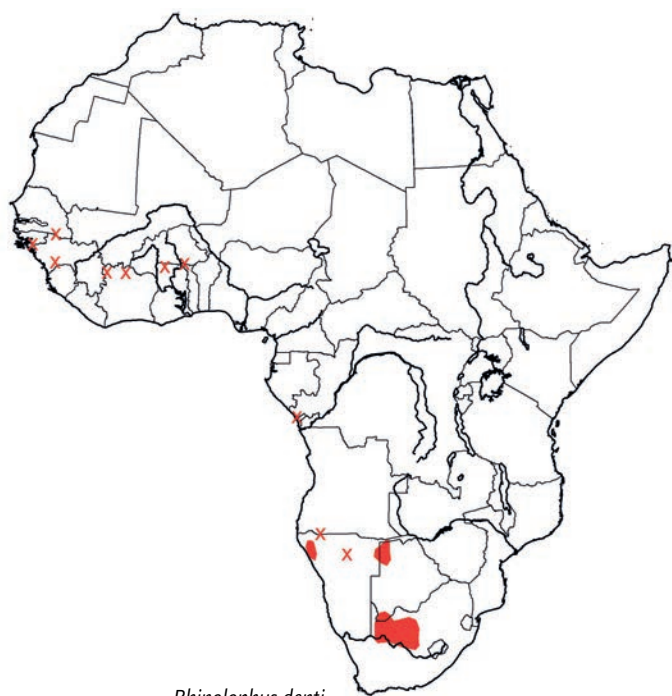

R. maendeleo. Larger (FA: 48, 49 mm). Known only from coastal forests of Tanzania.

Distribution Endemic to Africa. *Rhinolophus d. knorri* is known from the Sudan Savanna and Guinea Savanna BZs (with one record in the Rainforest–Savanna Mosaic) in West Africa: recorded from Guinea-Bissau, Guinea, Côte d'Ivoire and Ghana (Rosevear 1965; Csorba *et al.* 2003, Simmons 2005). Subsequently also recorded from Sierra Leone (Decher *et al.* 2010); not mapped. *Rhinolophus d. denti* is known from the South-West Arid BZ: recorded from S Angola, Namibia, NW and C Botswana, and Northern Cape Province of South Africa (Smithers 1971, Crawford-Cabral 1986, Taylor 2000). Records from Zambia and Mozambique in Csorba *et al.* (2003) are considered here to represent *R. swinyi*.

Habitat In West Africa, recorded from undifferentiated woodland, *Isobrerlinia* woodland and rainforest–savanna mosaic, with caves present at least at one locality. In southern Africa, recorded from semi-arid and desert vegetation zones including Bushy Karoo–Namib shrubland, Kalahari *Acacia* wooded grassland and the Namib Desert (terminology: White 1983). According to Smithers (1983), the availability of caves or rock crevices is probably more important than the type of vegetation.

Abundance Uncertain. Locally common in caves in Botswana and Namibia (Smithers 1971, Churchill *et al.* 1997).

Adaptations Not much information. *Rhinolophus d. knorri* has been found roosting by day in caves, under a bridge, and in a

Rhinolophus denti

hollow Kapok tree *Ceiba pentandra* (Eisentraut 1960, Grubb *et al.* 1998). *Rhinolophus d. denti* has been found roosting in caves, under the thatch roof of a house and in a culvert under a road (Shortridge 1934). In Drotsky's Caves (Botswana), found hanging freely from sides of stalactites; one colony in semi-darkness 90 m from entrance, another colony in pitch-darkness deep inside the cave (Smithers 1971). Roosts in these caves throughout the year. In Namibia, selects humid microclimates in caves (mean relative humidity 90.4%) and comparatively low temperatures (mean 24.4 °C) and enters torpor daily (Churchill *et al.* 1997). One was found roosting with a group of *Nycteris* (Shortridge 1934).

Foraging and Food No information. Observations made by Fenton (1985) refer to *R. swinnyi* (F. P. D. Cotterill unpubl.).

Echolocation No information. Echolocation calls attributed to *R.*

denti by Fenton (1975, 1985), Fenton & Bell (1981), Taylor (1999a) and Csorba *et al.* (2003) refer to *R. swinnyi* (F. P. D. Cotterill unpubl.).

Social and Reproductive Behaviour *Rhinolophus d. denti* has been found roosting singly, in twos and in small to large groups; two groups, each comprised of 'dozens' of individuals were located in Drotsky's Caves (Botswana); individuals were hanging in open clusters (Shortridge 1934, Smithers 1983).

Reproduction No information.

Predators, Parasites and Diseases Ectoparasites include bat-flies *Brachytarsina africana*, *Raymondia aspera* (Diptera: Streblidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

F. P. D. Cotterill

Rhinolophus eloquens ELOQUENT HORSESHOE BAT

Fr. Rhinolophe éloquent; Ger. Andersens Hufeisennase

Rhinolophus eloquens K. Andersen, 1905. Ann. Mag. Nat. Hist., ser. 7, 15: 74. Entebbe, Uganda.

Taxonomy Species-group: *fumigatus*. Synonyms: *perauritus*. Subspecies: two. Described as subspecies of *R. hildebrandtii*, but subsequently considered to be a distinct species by Andersen (1907), Allen (1939), Koopman (1975, 1994) and Csorba *et al.* (2003) although not by Hayman & Hill (1971), who treated *eloquens* as a subspecies of *R. fumigatus*. Chromosome number: not known.

Description Medium-small microbat with noseleaf (posterior component subtriangular with erect tip); medium-large for an African rhinolophid; anterior upper premolar displaced labially or absent; connecting process rounded; lancet subtriangular; sella

hairy with upper two-thirds parallel-sided; no axillary tufts; FA: 53–63 mm. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 7–9 mm. Dorsal pelage usually pale brown; hairs with dark grey at base. Ventral pelage paler than dorsal pelage. No orange-phase. No axillary tufts on adult ♂♂. Ears comparatively and relatively medium-short (21–38 mm, 47 [44–51]% of FA). Noseleaf with lancet long, subtriangular with sides slightly concave; tip rounded. Connecting process large, rounded, not higher than sella. Sella liberally covered with longish hairs, broad, upper two-thirds parallel-sided, top rounded. Horseshoe of medium breadth (11.1–12.3 mm), covering muzzle; lateral leaflets present, median emargination deep. Lower lip

with one groove. Wings and interfemoral membrane brown to dark greyish-brown. First phalanx of fourth finger relatively long (26.1 [23–28]% of fourth metacarpal, $n = 22$). Tibia 41.2 (37–44)% of FA, $n = 17$. Baculum trumpet-shaped with straight, cylindrical shaft, length 3.0 (2.8–3.2) mm, $n = 5$ (Cotterill 2002a).

Skull robust; zygomatic arches sturdy; zygomatic width much greater than mastoid width. Nasal swellings relatively high, longer than they are broad. Frontal depression shallow to moderately deep. Sagittal crest comparatively prominent anteriorly and usually extends some distance across parietals. Palatal bridge of medium relative length (32–37% of C–M³; Csorba *et al.* 2003). Anterior upper premolar minute and fully displaced labially, or absent; canine and posterior premolar in contact or almost so. Middle lower premolar usually absent; if present, fully displaced labially and lies under cingula of the anterior and posterior premolars, which overlap; anterior and posterior lower premolars in contact. Dental formula usually $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$, rarely $^{1123}/_{2133} = 32$ or $^{1113}/_{2133} = 30$.

Geographical Variation Koopman (1975, 1994), followed by Csorba *et al.* (2003) and Simmons (2005), recognizes two subspecies:

R. e. eloquens: S Sudan, E DR Congo, Uganda and N Tanzania, Pemba I. and Zanzibar I.

R. e. perauritus: S Somalia.

Similar Species Only two other *Rhinolophus* in Africa have the following combination of characters: anterior upper premolar displaced labially or absent; connecting process rounded and lower than the sella; sella hairy; horseshoe usually broader than 10 mm and as broad as the muzzle or almost so (Table 14, p. 304):

Rhinolophus fumigatus. Body measurements usually smaller, especially in areas of sympatry (Koopman 1975), (FA: 51 [47–60] mm). Skull smaller (CrnC: 22.7 [21.6–24.3] mm; C–M³: 8.0 [7.3–8.7] mm).

R. hildebrandtii. Usually larger (FA: 64 [60–67] mm; Tib: 26–31 mm; CrnC: 27.4 [26.1–28.7] mm). Baculum longer (>3.0 mm).

Distribution Endemic to Africa. Recorded mainly from the Somalia–Masai Bushland, Afromontane–Afroalpine and Coastal Forest Mosaic BZs in E DR Congo, Rwanda, E Uganda, Kenya, Somalia, N Tanzania, Pemba I., Zanzibar I. and Kirue I., with some records in the Sudan Savanna and Guinea Savanna BZs and the Rainforest–Savanna Mosaics in S Sudan and NE DR Congo (Koopman 1975, Aggundey & Schlitter 1984, Csorba *et al.* 2003). Specimens collected from Ntchisi F. R. and Liwonde N. P. (Malawi) by Happold & Happold (1997) include one specimen from each locality, which, based on echolocation CF-frequencies, probably represent *R. eloquens* (M. Happold pers. comm.); pending confirmation, neither locality has been mapped. Southern extent of distribution might also reach Zambia, Zimbabwe and N Mozambique (F. P. D. Cotterill & P. J. Taylor unpubl.). A specimen from Chano, S Ethiopia (not mapped), might represent *R. eloquens* (D. Kock in Yalden *et al.* 1996). Subsequently recorded from W, SW and S Uganda (Thorn & Kerbis Peterhans 2009) (not mapped): some of these records were previously considered to represent *R. hildebrandtii*.

Habitat Semi-arid savannas (including *Acacia–Commiphora* bushland and thicket, and mosaics of evergreen bushland and secondary

Rhinolophus eloquens

Acacia wooded grassland), mesic woodland savannas and montane forests. Both of the Malawian bats mentioned above were captured in miombo woodland at altitudes of 1500 m and 500 m, respectively.

Abundance Based on numbers in museum collections, locally common in E Uganda and Kenya; apparently scarcer elsewhere. Apparently less common than the sympatric *R. hildebrandtii*.

Adaptations Very little is known about this species. The literature almost certainly contains information about specimens that have been misidentified as *R. hildebrandtii* or *R. fumigatus*. One specimen from Malawi, provisionally identified as *R. eloquens* because it echolocated with CF-frequency 47.5 kHz (see Echolocation), had a low aspect ratio and low wing-loading (M. Happold pers. comm.).

Echolocation Echolocation call-shape FM/CF/FM. Echolocation calls from bats previously identified as *R. hildebrandtii* have CF-frequencies of 35–38 kHz (1 ♀, 7 ♂♂, hand-held) and 47–48 kHz (2 ♀, hand-held) (Malawi; M. Happold pers. comm.); 37 kHz and 46 kHz ($n = 2$, flying in open) (Zimbabwe, Fenton & Bell 1981), and ca. 40 kHz ($n = 9$, flying in room or in open) (Kruger N. P., South Africa, Aldridge & Rautenbach 1987). It is probable that the lower-frequency calls are made by the larger *R. hildebrandtii*, and that the higher-frequency calls are made by the smaller *R. eloquens* or a closely related form (F. P. D. Cotterill, M. Happold & P. J. Taylor unpubl.). The acoustics of the vocal tract, and the role of the tracheal chambers and nasal cavities, of bats from Zimbabwe identified as *R. hildebrandtii* (but with CF-frequency ca. 48 kHz), were investigated by Suthers *et al.* (1988) and Hartley & Suthers (1988) (see Family Rhinolophidae).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure No information.

Predators, Parasites and Diseases Ectoparasites include a flea *Rhinolophopsylla ectopa* (Siphonaptera: Ischnopsyllidae) (Beaucournu & Kock 1996). Some of the ectoparasites listed as hosted by *R. hildebrandtii* by Anciaux de Faveaux (1984) were hosted by *R. eloquens* (see profile of *R. hildebrandtii*). Mt Elgon bat virus was isolated from salivary glands (Metselaar *et al.* 1969).

Conservation IUCN Category: Least Concern.

Rhinolophus euryale MEDITERRANEAN HORSESHOE BAT

Fr. Rhinolophe euryale; Ger. Mittelmeer-Hufeisennase

Rhinolophus euryale Blasius, 1853. Arch. Naturgesch. 19 (1): 49. Milan, Italy.

Taxonomy Species-group: *euryale*. Synonyms in Africa: *algirus*, *barbarus*, *meridionalis* (extralimitally: *atlanticus*, *cabreræ*, *judaicus*, *nordmanni*, *toscanus*). The form *tuneti* from Tunisia is currently included in *R. mehelyi*. Subspecies: possibly two of which only the nominate occurs in Africa (see Geographic Variation). Chromosome number (Europe): 2n = 58; aFN = 60 (Manfredi Romanini *et al.* 1975). There are four metacentric and 52 acrocentric autosomes, X = large metacentric, Y = very small metacentric, acrocentric or dot-like (Zima 1982, Zima *et al.* 1992).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar within tooththrow; connecting process rising to high horn; sella parallel-sided; no axillary tufts; first phalanx of fourth finger relatively short; marked contrast between the crown areas of the anterior and posterior lower premolars (cf. *R. blasii*); faint spectacles around eyes (cf. *R. mehelyi*). Not easily distinguished from *R. mehelyi*. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 7–9 mm. Dorsal pelage greyish-brown with slight reddish, lilac or yellowish tinge (juveniles grey); hairs of adults whitish with greyish-brown at tip. Ventral pelage paler to considerably paler (but never almost white); boundary with dorsal pelage indistinct. Usually some brown hairs around eyes, but ‘spectacles’ comparatively faint (cf. *R. mehelyi*). No orange-phase. No axillary tufts on adult ♂♂. Ears comparatively and relatively short (19–22 mm, mean E ca. 42% of mean FA). Noseleaf with lancet subtriangular, tip bluntly pointed. Connecting process rising to high, narrow, forward-curving, pointed horn (Figure 59k). Sella naked, almost parallel-sided, top broad, rounded and tilted forward. Horseshoe narrow (6.5–7.5 mm), not covering whole muzzle; no lateral leaflets; median emargination shallow. Lower lip with three grooves. Wings and inter-femoral membrane pale brown. First phalanx of fourth finger relatively short (20.0 [17–22]% of fourth metacarpal, n = 22), and <50% of second phalanx (cf. most *R. blasii*). Tibia 43 (41–45)% of FA, n = 4.

Skull delicate; zygomatic and mastoid widths usually nearly equal but sometimes one or the other is the widest. Rostrum narrow; nasal

swellings relatively low. Frontal depression shallow; supraorbital crests poorly developed. Sagittal crest absent or very low. Bar between infraorbital foramen and orbit short and broad, infraorbital foramen small (cf. *R. mehelyi*). Palatal bridge of medium relative length (31–35% of C–M³; Csorba *et al.* 2003). Anterior upper premolar small, within tooththrow; canine and posterior premolar well separated. Middle lower premolar very small, somewhat displaced labially; anterior and posterior lower premolars separated. Crown area of lower anterior premolar 50% or less of that of the posterior premolar. Dental formula ¹¹²³/₂₁₃₃ = 32.

Geographic Variation Currently, only the nominate subspecies is considered to occur in Africa (Kowalski & Rzebiak-Kowalska 1991, Horáček *et al.* 2000, Csorba *et al.* 2003). Extralimitally, *R. e. judaicus* (E Mediterranean) is considered to be the only other valid subspecies by Csorba *et al.* (2003) and Simmons (2005), but its validity is questioned by Harrison & Bates (1991).

Similar Species Only one other *Rhinolophus* in Africa has a connecting process which rises to a high narrow pointed horn (Table 14, p. 304):

Rhinolophus blasii. Sella wedge-shaped; horseshoe usually broader (7.2–9.0 mm). First phalanx of fourth finger relatively long (24–28% of fourth metacarpal). No marked contrast between crown areas of anterior and posterior lower premolars.

One sympatric species has a triangular connecting process that, although lower, also rises to a point:

R. mehelyi. Lancet hastate with distal half narrow, almost parallel-sided but slightly tapering to a thin apex. Eyes usually with dark spectacles or a dark patch under each eye; dorsal hairs with pale greyish-beige bases; ventral pelage almost white or pure white. Craniodental characters almost indistinguishable.

Distribution In Africa, recorded from the Mediterranean Coastal BZ (and marginally from the Sahara Arid BZ) in NW Africa, from Morocco through Algeria to Tunisia. Extends southwards to ca. 32°N in Morocco (Aulagnier & Thévenot 1986) and 34° 25'N in Tunisia (Aellen & Strinati 1969) but as yet recorded from only three localities close to the coast in Algeria (Kowalski & Rzebik-Kowalska 1991) although likely to occur further inland in some areas. Extraliminally: France and Portugal to Turkmenistan and Iran, and also Arabian Peninsula (Horáček *et al.* 2000, Hutson *et al.* 2001).

Habitat In NW Africa, recorded from Mediterranean sclerophyllous forest, sub-Mediterranean semi-desert grassland and shrubland, and transitional zones (terminology: White 1983). Prefers limestone areas with numerous caves and water nearby.

Abundance Rare in Algeria and Tunisia, common in certain areas of N Morocco.

Adaptations Aspect ratio low; wing-loading low (Gaisler 1959). Flight slow, fluttering, very manoeuvrable. Can hover. In NW Africa, apparently roosts by day only in caves but, in Europe, also roosts in buildings. Usually does not wrap the wings completely around the body, even during hibernation. In summer, roosts deep inside caves at ambient temperature of 22 °C (Morocco), 20–26 °C (Algeria); sometimes shares roosts with *Rhinolophus blasii*, *Myotis emarginatus*, *M. punicus* and/or *Miniopterus schreibersii*. In winter, hibernates at roosts near the entrances of caves at ambient temperatures of 10–12.5 °C (Morocco) (Aulagnier & Thévenot 1986, Gaisler 2001a). In Lebanon, hibernating individuals hang singly (Atallah 1977). In Europe, usually sedentary; greatest recorded movement 134 km (Schober & Grimmberger 1989).

Foraging and Food No data from Africa. In Europe, leaves day-roosts in late dusk; forages low over ground; preys on moths and

other insects (Schober & Grimmberger 1989, Gaisler 2001a). Often takes prey to a night-roost where it is consumed.

Echolocation Call-shape FM/CF/FM. CF-frequency 101–108 kHz; duration ca. 20–30 ms (Schober & Grimmberger 1989).

Social and Reproductive Behaviour Roosts in groups (colonies) of varying size and composition depending on season. Extraliminally, roosts in colonies of up to 2000 individuals of both sexes during winter; and forms maternity colonies of 50–400 ♀♀ in summer; ♂♂ sometimes present in the maternity colonies. In Algeria, assemblages of up to 200 individuals of both sexes were recorded at one cave in spring and also in autumn but, in mid-winter, this cave was not inhabited by *R. euryale*, and in summer it was only inhabited sporadically by ♂♂ (Kowalski *et al.* 1986). Individuals roosted singly if torpid, or in associations, often in contact with neighbours, if they were active. In Morocco, colonies comprised of several dozens of ♀♀ were noted at the time of 'reproduction' (Brosset 1955 in Aulagnier & Thévenot 1986).

Reproduction and Population Structure Litter-size: probably one (as in Europe). In Europe, births occur in summer (Jun–Jul); no detailed information. Sexual maturity: ♂♂ at 15 months to 2¼ years; ♀♀ at 2–3 years (Gaisler 2001a).

Predators, Parasites and Diseases Ectoparasites (North Africa) include a flea *Rhinolophopsylla unipunctinata arabs* (Siphonaptera: Ischnopsyllidae); bat-flies *Nycteribia latreillei*, *N. vexata*, *Penicillidia dufouri*, *Phthiridium biarticulatum* (Diptera: Nycteribiidae) and *Brachytarsina africana* (Diptera: Streblidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Near Threatened.

The global population appears stable and/or even increasing in some areas.

Rhinolophus euryale

Jiří Gaisler

Rhinolophus ferrumequinum GREATER HORSESHOE BAT

Fr. Grand rhinolophe; Ger. Große Hufeisennase

Rhinolophus ferrumequinum (Schreber, 1774). Die Säugethiere 1: 174, pl. 62. France.

Taxonomy Originally *Vespertilio ferrum-equinum*. Species-group: *ferrumequinum*. Synonyms in Africa: one (extraliminally 33 others listed by Simmons [2005]). Subspecies: only the nominate subspecies occurs in Africa; extraliminally, six others recognized by Simmons (2005) but subspecies limits are unclear, the validities of some are dubious, and more than one species might be represented (Horáček *et al.* 2000, Csorba *et al.* 2003). Chromosome number (Tunisia): $2n = 58$; $aFN = 60$ (Baker *et al.* 1975). There are usually 4–6 metacentric and 50–52 acrocentric autosomes, $X =$ large, metacentric or submetacentric, $Y =$ very small, acrocentric, metacentric or dot-like (Zima 1982, Zima *et al.* 1992).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar displaced labially or absent; connecting process rounded; lancet hastate; sella with concave sides; no axillary tufts. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 9–11 mm. Dorsal pelage greyish-brown or brown, more or less tinged with red (juveniles ashy-grey); hairs of adults beige with greyish-brown or brown at tip. Ventral pelage greyish-white to yellowish-white. No orange-phase. No axillary tufts on adult ♂♂. Ears comparatively medium-short (19–25 mm) and relatively short (mean E 41% of mean FA). Noseleaf with lancet hastate (Figure 61e) or subtriangular becoming slightly concave near tip, tip bluntly pointed. Connecting process rounded, much higher than sella. Sella naked, relatively small and curved forward so front surface is strongly concave, sides slightly concave, top broad and rounded. Horseshoe narrow (7.0–9.0 mm in Africa), not covering whole muzzle; lateral leaflets present but sometimes inconspicuous; median emargination deep. Lower lip with one or three grooves (lateral grooves sometimes inconspicuous). Wings and interfemoral membrane pale brown or greyish-brown. First phalanx of fourth finger relatively long (27.6 [24–31]% of fourth metacarpal, $n = 39$) and <50% of second phalanx (cf. *R. blasii*). Tibia 44.8 (44–46)% of FA, $n = 6$.

Skull robust; zygomatic arches sturdy; zygomatic width greater than mastoid width. Nasal swellings of medium-low relative height. Frontal depression shallow; supraorbital crests weak. Sagittal crest well developed anteriorly, absent posteriorly. Palatal bridge 28–35% of $C-M^3$ (Csorba *et al.* 2003). Anterior upper premolar minute and fully displaced labially, or absent; canine and posterior premolar in contact. Middle lower premolar minute and fully displaced labially, or absent; anterior and posterior lower premolars in contact. Dental formula $^{1123}/_{2133} = 32$, $^{1113}/_{2133} = 30$, $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$.

Geographic Variation *Rhinolophus f. ferrumequinum* is the only subspecies in Africa (Aulagnier & Thévenot 1986, Csorba *et al.* 2003, Simmons 2005). No variation has been recorded in Africa, but a clinal trend in size is manifested by populations of this subspecies in Europe: size increases from west to east in the Mediterranean region (including the Maghreb in NW Africa), and from north-west to south-east in Eastern Europe (Kryštufek 1993, de Paz 1995).

Similar Species Only one other *Rhinolophus* found in North Africa has the anterior upper premolar fully displaced labially or absent, and the connecting process rounded (Table 14, p. 304):

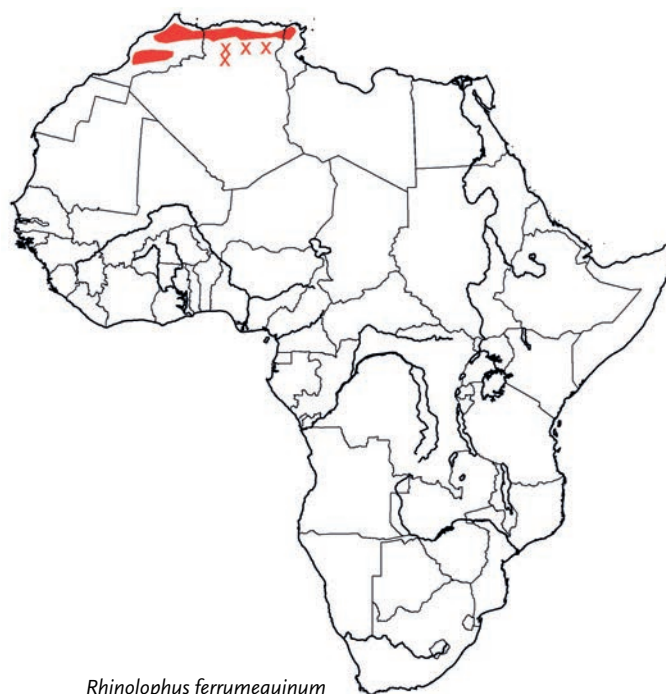

Rhinolophus clivosus. Not recorded from NW Africa, therefore not sympatric. In S Algeria, Libya and Egypt, forearm shorter (46.1 [43–49] mm).

Distribution In Africa, found in the Mediterranean Coastal and Afromontane–Afroalpine BZs (and very marginally in the Sahara Arid BZ) in the Maghreb (NW Africa). Recorded from Morocco (coast to Anti Atlas at 31°N), Algeria (coast to southern border of Saharan Atlas at 33°N) and Tunisia (coast to northern border of Sahara). Possibly occurs in Mediterranean Libya (but not yet recorded). Subsequently recorded as far south as 32° 55'N in Tunisia (Dalhoumi *et al.* 2011); not mapped. Extraliminally: Western Europe to China, Korea and Japan, also Arabian Peninsula and Indian sub-continent.

Habitat In Africa, these cave-roosting bats inhabit rocky regions with sparse vegetation, either primary or secondary (macchia or garrigue), from sea level to at least 1500 m (Brezina, Saharan Atlas, Algeria).

Abundance Common and widely distributed in the northern (Mediterranean) zone of Morocco, Algeria and Tunisia where caves and other underground spaces are abundant. Less common in the middle zone of the Hauts Plateaux.

Adaptations A particularly well-studied species extraliminally, but comparatively little information from Africa. Aspect ratio low; wing-

Rhinolophus ferrumequinum

loading medium; wing-tip rounded and short (Norberg & Rayner 1987). Flight slow, manoeuvrable, fluttering, with some glides; can hover briefly and take off from ground. Usually flies low (0.5–6 m above ground). Mean flight speed (indoors) 5.5 m/s (Norberg 1987). In Africa, roosts by day in caves and other subterranean spaces such as rhattaras (underground irrigation channels); hangs from walls or ceilings. Roosts in warmer galleries in summer; in contrast to Europe, African populations do not seem to use buildings in summer, and even maternity colonies are in caves. Males, and ♀♀ which are neither pregnant nor lactating, become torpid during the day when temperature is 22 °C or less. Summer-roosts that are not maternity roosts are often shared with other *Rhinolophus* spp., *Miniopterus schreibersii* or *Myotis* spp. and, in Morocco, also with *Asellia tridens* and *Plecotus gaisleri*. Maternity roosts are sometimes shared with other species. In winter, hibernates in cool parts of caves. Certain caves are inhabited all year round, others just in summer and others only in winter. Distance between summer- and winter-roosts does not exceed 35 km (Gaisler 2001b). Individuals wrap themselves completely in their wing-membranes during hibernation.

Foraging and Food Forages by slow-hawking, fly-catching and ground-gleaning (Norberg & Rayner 1987, Jones & Rayner 1989a, Schober & Grimmberger 1989, Duvergé & Jones 1994, Jones *et al.* 1995). Flying insects often caught by the tip of the bat's wing-membrane. Sometimes lands to take dung-beetles and other insects from cow dung. Some insects are eaten on wing; others are taken to a perch and eaten there. Forages in terrain with sparse tree cover, on hillsides, cliff faces, and in gardens (Europe). Supposedly foraging individuals were mist-netted at six localities in Algeria, mostly among bushes and close to rocks or water (Gaisler & Kowalski 1986). Activity is strictly nocturnal; individuals typically leave day-roosts 15–30 min after sunset, and begin foraging soon after. They usually linger close to their roosts before foraging further afield; foraging individuals stay outside the day-roost for the whole night, or return after 2–3 h and leave the day-roost again for 30–50 min before sunrise. Some rest in night-roosts close to their foraging areas. Extraliminally, Lepidoptera and Coleoptera were found to prevail in diet; Hymenoptera, Diptera and Araneae were rare.

Echolocation Call-shape usually FM/CF/FM. CF-frequency 80 (77–83) kHz; call-duration ca. 40 ms (Schober & Grimmberger 1989, Limpens & Roschen 1995; country not given, probably Southern Europe). In England, found to use harmonics other than the dominant second harmonic, and to modify the call-shape according to the bat's activity (Jones & Rayner 1989a). When flying (e.g. leaving the day-roost or foraging) call-shape is FM/CF/FM and the terminal descending FM sweep usually has the greater bandwidth. When perch-hunting, in ca. 49% of calls, the ascending and descending FM sweeps have roughly equal bandwidths, and ca. 35% have no discernible FM sweeps.

Social and Reproductive Behaviour Forages singly; juveniles forage independently of their mothers prior to weaning. Roosts singly, in small groups or in very large groups (colonies). Extraliminally, winter colonies contain up to 500 individuals of both sexes. In summer, pregnant ♀♀ form maternity colonies containing up to 400 ♀♀; some immature and non-breeding individuals of both sexes roost with these ♀♀; adult ♂♂ may be present initially, but usually depart when parturition begins, and subsequently roost in small, scattered groups. A colony of juveniles separated from adults, and an all-male colony, were

recorded in Algeria. In Europe, adult ♂♂ and ♀♀ begin roosting together in late summer; copulations take place at the day-roosts and occur until the end of October. During these times, ♂♂ are territorial and, as in many other cave-roosting bats, they establish small harems. Typically, a single cave contains many discrete mating-roosts, each occupied by one ♂ and up to eight ♀♀. Females not inseminated during this time can copulate later in winter or soon after the end of hibernation in spring (Gaisler 2001b).

Reproduction and Population Structure Litter-size: one. At 35–36°N in NW Algeria, the reproductive chronology is restricted seasonal monoestry, with births in summer (Jun), volant young appearing in late Aug, and lactation lasting until early Sep (Kowalski *et al.* 1986). In Europe, sperm-storage occurs in the epididymides of the ♂ and also in the ♀ oviducts until ovulation and fertilization take place in Mar–Apr. The interval between fertilization and birth varies from 2 to 3 months, depending on whether embryonic development is lengthened because of torpor in the pregnant ♀♀ (Ransome 1973). Females are 3–5 years old when they produce their first young. Pubic nipples are not fully developed until after first birth. Males mature when 2–4 years old. Extraliminally, longevity is up to 30 years 6 months (♂♂) and 27 years 8 months (♀♀).

Predators, Parasites and Diseases Predators in Africa not known. In Europe, preyed on, rarely, by owls *Tyto alba* and *Strix aluco*. Individuals emerging at dusk are sometimes taken by Sparrowhawks *Accipiter nisus* (Jones *et al.* 1995). Ectoparasites in Africa include fleas *Ischnopsylla octactena*, *Rhinolophopsylla unipectinata* (Siphonaptera: Ischnopsyllidae); bat-flies *Nycteribia schmidli*, *Penicillidia dufouri*, *Phthiridium biarticulatum* (Diptera: Nycteribiidae), *Brachytarsina kollari* (Diptera: Streblidae) and two species of mites (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern (assessed from extralimital as well as African data).

Rhinolophus fumigatus RÜPPELL'S HORSESHOE BAT

Fr. Rhinolophe de Rüppell; Ger. Rüppells Hufeisennase

Rhinolophus fumigatus Rüppell, 1842. Mus. Senckenbergianum 3: 132, 155. Shoa, Ethiopia.

Taxonomy Species-group: *fumigatus*. Synonyms: *abae*, *acrotis* G. M. Allen, 1914, *aethiops*, *antinnorii*, *diversus*, *exsul*, *foxi*, *macrocephalus*. Subspecies: six. The status and geographic ranges of several of these taxa are uncertain (see Geographic Variation); revision needed. Variation (especially in size) suggests that more than one species is contained within *R. fumigatus* (Rosevear 1965, Csorba *et al.* 2003), possibly as many as four. However, it is not yet known to what extent variation in *R. fumigatus* reflects clinal variation and character displacement (see Geographic Variation). Chromosome number (*R. f. aethiops*: South Africa): $2n = 58$; $aFN = 62$. $X =$ large subtelocentric, $Y =$ small metacentric (Rautenbach 1986).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium to fairly large for an African rhinolophid; anterior upper premolar displaced labially or absent; connecting process rounded; lancet subtriangular; sella hairy; no axillary tufts. Sexes similar. Pelage dense, soft, fluffy; mid-dorsal hairs 8–9 mm. Dorsal pelage grey to greyish-brown; hairs greyish-fawn to pale greyish-brown, darker at tip. Ventral pelage slightly paler. Apparently no orange-phase. No axillary tufts on adult ♂♂. Ears comparatively and relatively medium–short (19–28 mm ♂♂, 46 [40–51]% of FA, $n = 27$). Noseleaf with lancet subtriangular, sides slightly concave, tip rounded. Connecting process large, rounded, not higher than sella. Sella liberally covered with longish hairs, broad, sides slightly concave or almost parallel; top broad and rounded. Horseshoe of medium breadth (9.6–11.5 mm); almost covering muzzle; lateral leaflets present; median emargination a distinct notch. Lower lip with one groove. Wings and interfemoral membrane dark grey to dark brown. First phalanx of fourth finger relatively long (25.8 [24–28]% of fourth metacarpal, $n = 18$). Tibia 42 (39–45)% of FA, $n = 35$. Baculum trumpet-shaped with round shaft, length 2.9 (2.7–3.1) mm, $n = 11$ (Cotterill 2002a).

Skull robust; zygomatic arches moderately slender; zygomatic width much greater than mastoid width. Rostrum sturdy. Nasal swellings of medium relative height; broader than they are long. Frontal depression shallow to moderately deep, supraorbital ridges pronounced. Sagittal crest well developed anteriorly, low or absent posteriorly. Interpterygoid groove distinct and narrowed medially. Palatal bridge relative length variable (28–37% of $C-M^3$; Csorba *et al.* 2003). Anterior upper premolar minute and fully displaced labially, or absent; canine and posterior premolar in contact. Middle lower premolar absent except rarely; anterior and posterior lower premolars in contact. Dental formula usually $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$, rarely $^{1123}/_{2133} = 32$ or $^{1113}/_{2133} = 30$.

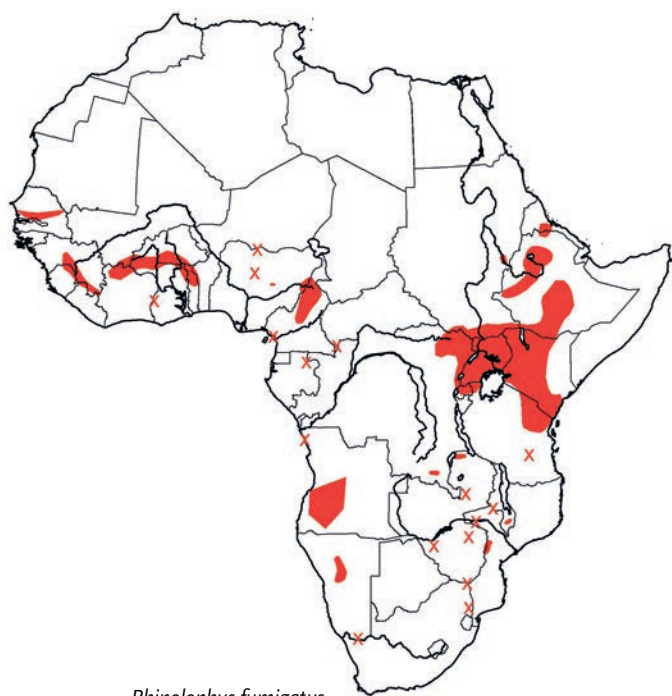

Geographic Variation Six forms are tentatively treated as subspecies (following Koopman 1975, 1994, Csorba *et al.* 2003, Simmons 2005), but their status, geographic ranges and the extent to which variation is clinal are uncertain (Rosevear 1965, Koopman 1994, Csorba *et al.* 2003):

- R. f. diversus*: West Africa: Senegal to Sierra Leone (Koopman 1994). FA: 53–55 mm; CrnC: 23–24 mm (Rosevear 1965). Possibly a distinct species, or a subspecies of *R. aethiops* (see below).
- R. f. foxi*: West Africa: Burkina (and perhaps Côte d'Ivoire) to Central African Republic (Koopman 1994). FA: 50.1 (47–54) mm, $n = 53$; CrnC: 22.5 (21.5–23.8) mm. Possibly a distinct species.
- R. f. fumigatus*: Eritrea and N and C Ethiopia. FA: 49–53 mm; CrnC: 21.5–22.6 mm (Rosevear 1965).
- R. f. abae*: NE DR Congo, W Uganda and extreme SW Sudan (F. P. D. Cotterill unpubl.). FA: 53 (50–54) mm, $n = 10$; CrnC 23 (21.9–23.6) mm, $n = 10$ (Allen 1917a). Very closely related to *exsul* (Koopman 1965) and both *abae* and *exsul* are closer to *fumigatus* than to *aethiops* (Koopman 1966). Possibly *abae* and *exsul* exhibit clinal variation across equatorial Africa from NE DR Congo to the east coast (F. P. D. Cotterill unpubl.).
- R. f. exsul*: eastern Africa from C Sudan, S Ethiopia, E Uganda, Kenya and Tanzania (Koopman 1994), and apparently Malawi as far southwards as Zomba (Happold *et al.* 1987, Ansell & Dowsett 1988). FA: 51.4 (48–55) mm, $n = 21$; CrnC: 22.8 (21.6–23.9) mm, $n = 31$.
- R. f. aethiops*: southern Africa from S Angola to C Mozambique and southwards to Cape Province of South Africa (Meester *et al.* 1986). FA: 55–60 mm, CrnC: 23–25.1 mm (Rosevear 1965). Possibly a distinct species; if distinct, perhaps contains *diversus* as subspecies (J. E. Hill in Grubb *et al.* 1998).

Similar Species Only two other *Rhinolophus* in Africa have the following combination of characters: anterior upper premolar displaced labially or absent; connecting process rounded and lower than the sella; sella hairy; horseshoe usually broader than 10 mm and as broad as the muzzle or almost so (Table 14, p. 304):

- Rhinolophus eloquens*. Body measurements usually larger, especially in areas of sympatry (Koopman 1975) (FA: 53–63 mm). Skull larger (CrnC: 23.8–26.2 mm; $C-M^3$: 9.2 [8.7–9.6] mm).
- R. hildebrandtii*. Larger (FA: 60–67 mm; Tib: 26–31 mm; CrnC: 26.1–28.7 mm). Anterior median nasal swellings longer than they are broad.

Distribution Endemic to Africa. Mainly recorded from the Sudan Savanna, Guinea Savanna, Afromontane–Afroalpine, Somalia–Masai Bushland, Coastal Forest Mosaic and Zambezian Woodland BZs, and from the Rainforest–Savanna Mosaics. Also a few records in the Rainforest BZ and South-West Arid BZ. In the west, there are scattered records from Senegal to Cameroon and N Congo and southwards to Angola and Namibia. In the east, recorded disjunctly from Eritrea, Ethiopia and EC and S Sudan to NE South Africa. Probably more widespread than records indicate; many of the gaps probably reflect insufficient sampling. Not yet recorded from NE Botswana but likely to occur there. Mapped from country checklists (see order Chiroptera), other literature and museum records.

*Rhinolophus fumigatus*

Habitat Savannas, including undifferentiated woodland and *Isoberlinia* woodland in West Africa, *Acacia*–*Commiphora* bushland and thicket in East Africa, and miombo and mopane woodlands in south-central Africa, where suitable day-roosts are available. Absent from true moist forest, and deserts.

Abundance Based on museum specimens, locally common in West Africa. Commonly recorded in Malawi (Happold & Happold 1997); rarer in Zimbabwe.

Adaptations Aspect ratio low; wing-loading low; wing-tip rounded (Malawi; M. Happold unpubl.). Flight variable in speed and highly manoeuvrable. Can take off from ground; probably cannot hover. Turns by banking (minimum radius <25 cm), and by stalling-and-twisting; individuals sustained flight within a 1×1×1 m enclosure for up to five circuits/flight (5 bats, 10 flights each; M. Happold unpubl.). Day roosts include caves, cavities and narrow crevices in piles of boulders, mine-adits, hollow baobab trees *Adansonia* and occasionally houses and tobacco barns (Rosevear 1965, Smithers & Wilson 1979, Smithers 1983). Hangs freely from ceilings; body completely enclosed by wings. Roosts in complete darkness or in dimly lit places. In Malawi, sometimes shares day-roosts with *R. simulator* and *Nycteris thebaica*. In Namibian caves, selects roost-sites where temperature (± 1 S.D.) is 25.6 ± 1.05 (24–27) °C and relative humidity is 69 ± 13 (55–94)%, and enters torpor during the day (Churchill *et al.* 1997). Captive bats in Malawi also were torpid during the day at ambient temperature 21–24 °C (Happold & Happold 1988). Predicted mean maximum urine concentration is comparatively low (3122 mOsmol/kg); captive bats drank several times each night (they landed beside water and drank by lapping and sucking) (Happold & Happold 1988).

Foraging and Food Forages by fly-catching and slow-hawking (Shortridge 1934, Grubb *et al.* 1998), and also predictably by gleaning. One fly-catching individual foraged for moths from a perch

at the end of a branch ca. 3 m above ground; same perch used the following night (Shortridge 1934). Diet includes small to medium-sized beetles, moths and other insects (Aldridge & Rautenbach 1987).

Echolocation Call-shape FM/CF/FM. In Malawi, CF-frequency 55–58 kHz ($n = 8$ ♀♀ and 1 ♂ hand-held, 1 ♀ released in the field, 2 ♀♀ tethered); maximum variation by a hand-held individual was 3 kHz. In the wild, CF-frequencies 55–59 kHz were emitted by 13 bats flying together in a cave, and 53–56 kHz were emitted by three bats flying in the open. The low values in the open suggest that the bats were using Doppler shift compensation in this situation. Call-duration 36–53 ms (nine hand-held bats; 699 calls), 59–67 ms (three bats flying low in the wild), 29–44 ms (many bats flying in a cave) (M. Happold unpubl.). In Kruger N. P. (South Africa), CF-frequency 55 kHz (Aldridge & Rautenbach 1987). CF-frequencies 45–50 kHz were recorded in Uganda by Pye & Roberts (1970), but these overlap the CF-frequencies of *R. hildebrandtii*, suggesting that the Ugandan specimens were misidentified.

Social and Reproductive Behaviour Roosts singly or in small to very large groups. Groups of ca. 10–50 seen in Malawi; rarely more than 10 in Zimbabwe; found singly and in groups of 25–500 in N Namibia (Churchill *et al.* 1997). Group-members hang in close contact with neighbours. Five individuals captured from a group of ca. 12 in Cameroon, were all ♀♀ (Aellen 1952) and some samples taken from groups in Malawi contained only pregnant and/or lactating ♀♀; this suggests that maternity colonies are established.

Reproduction and Population Structure Litter-size: one ($n = 14$). In Malawi and southern Africa, the reproductive chronology is probably restricted seasonal monoestry. At 14–15°S in Malawi, 1 of 1 ♀♀ was pregnant in Sep; 8 of 8 pregnant and in close reproductive synchrony in early Nov; 3 of 3 lactating in mid-Nov; 1 of 3 pregnant and 2 of 3 lactating in Dec; and 3 of 3 neither palpably pregnant, nor lactating, in Apr–May. Juveniles reported Dec–Mar. No data for other months. These data are consistent with restricted seasonal monoestry with births at beginning of wet season (Nov–Dec) (Happold & Happold 1990a, M. Happold unpubl.). In Zimbabwe, pregnant ♀♀ are reported in Sep–Oct (Smithers 1983) and (in NE Zimbabwe) lactation in Nov–Jan; ♀♀ found during cool-dry season were neither visibly pregnant nor lactating (F. P. D. Cotterill unpubl.); these data are also consistent with restricted seasonal monoestry with births in Nov–Dec.

Predators, Parasites and Diseases Predators include Spotted Eagle-owls *Bubo africanus* (Demeter 1982). Ectoparasites include a bug *Adroctenes horvathi* (Hemiptera: Polytectenidae), bat-flies *Penicillidia fulvida*, *P. pachymela*, *Phthiridium scissum*, *P. hoogstraali* (Diptera: Nycteribiidae), *Ascodipteron brevior*, *Brachytarsina africana*, *Raymondia intermedia*, *R. seminuda* (Diptera: Streblidae); two species of ticks (Argasidae, Ixodidae) and eight species of mites (Spinturnicidae, Macronyssidae, Leeuwenhoekidae, Psorergatidae, Chirodiscidae, Sarcopitidae) (Anciaux de Faveaux 1984, Kock *et al.* 1998b).

Conservation IUCN Category: Least Concern.

Rhinolophus guineensis GUINEAN HORSESHOE BAT

Fr. Rhinolophe de Guinée; Ger. Guinea-Hufeisennase

Rhinolophus guineensis Eisentraut, 1960. Stuttgarter Beitr. Naturk. (39): 1. Near Tahiré, base of Kelesi Plateau, 500 m, Guinea.

Taxonomy Originally *Rhinolophus landeri guineensis*. Species-group: *landeri*. Synonyms: none. Raised to species rank by Böhme & Hutterer (1978) based on sympatric occurrence in Sierra Leone (Rosevear 1965). Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-small for an African rhinolophid; anterior upper premolar within tooththrow; connecting process subtriangular; lancet hastate; sella parallel-sided; first phalanx of fourth finger relatively short; tibia 21–22 mm. Sexes similar in body measurements but ♂♂, on average, larger craniodentally. Pelage soft, fluffy; mid-dorsal hairs 7–8 mm. Dorsal pelage brown to greyish-brown, sepia brown, orange-brown or pale reddish-brown; hairs with tip darker than base. Ventral pelage slightly paler. No orange-phase known. Axillary tufts in ♂♂, when present, usually white although in one case reddish-brown (Eisentraut 1960, Böhme & Hutterer 1978). Ears comparatively and relatively short (17–22 mm, 41.3 [38–47]% of FA), each with 11–12 internal folds. Noseleaf with lancet hastate. Connecting process subtriangular in profile; tip pointed (Figure 59g). Sella naked and parallel-sided. Horseshoe narrow (8.3–9.3 mm); no lateral leaflets; median emargination present. Lower lip with one groove. Wings and interfemoral membrane dark grey. First phalanx of fourth finger relatively short (19.6 [17–21]% of fourth metacarpal, n = 11). Tibia 45.4 (42–48)% of FA, n = 12.

Skull of medium build, zygomatic arches moderately broad; zygomatic width slightly greater than mastoid width. Nasal swellings relatively narrow but high. Frontal depression shallow. Palatal bridge 26–31% of C–M³ (Csorba *et al.* 2003). Anterior upper premolar comparatively large, within tooththrow or only slightly displaced labially; canine and posterior premolar well separated. Middle lower premolar very small to vestigial, fully displaced labially; anterior and posterior lower premolars in contact. Anterior lower premolar smaller than posterior lower premolar and only ca. half of its height, or less (cf. *R. l. landeri*). Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation None.

Similar Species Only two other *Rhinolophus* in sub-Saharan Africa have the following combination of characters: anterior upper premolar within tooththrow; connecting process triangular and pointed; first phalanx of fourth finger relatively short; axillary tufts in ♂♂ usually present (Table 14, p. 304):

Rhinolophus landeri. Usually smaller, especially in West Africa where FA: 39–45 mm, Tib: 17–21 mm, CrnC: 16.9–18.9 mm, C–M³: 6.3–7.0 mm. Anterior lower premolar larger, more than half and usually two-thirds of the height of the posterior premolar. Axillary tufts in ♂♂ usually reddish or reddish-brown. Horseshoe narrower (6.0–8.0 mm).

R. alcyone. Body measurements usually larger (FA: 48–56 mm, Tib: 21–27 mm). Skull larger (CrnC: 21.0–23.3 mm, C–M³: 7.9–9.2 mm). Sagittal crest more developed. Axillary tufts in ♂♂ usually orange-red or brown.

Distribution Endemic to Africa. Recorded mainly from the Afromontane–Afroalpine BZ, Rainforest BZ and Northern Rainforest–Savanna Mosaic (and very marginally from the Sudan Savanna BZ). Known from only 15 localities within an area of ca. 180,000 km². The distribution follows the highlands from the Man region in Côte d'Ivoire (Déoulé waterfall, FMNH; published by Csorba *et al.* 2003, as *R. landeri*) through Mt Nimba to Liberia, Sierra Leone and the Fouta Djallon in Guinea (Eisentraut & Knorr 1957, Eisentraut 1960, Brosset 1984, Koopman 1989, Koopman *et al.* 1995, J. Fahr unpubl.). There are also two fairly isolated records in S Senegal (Böhme & Hutterer 1978). Several records from Guinea (Darsalam, Nyembaro, Tahiré) and Sierra Leone (Makeni) referred to *R. landeri guineensis* by Rosevear (1965) are listed erroneously by Csorba *et al.* (2003) under *R. landeri*.

Habitat Sub-montane to montane forests in highlands of Guinea, Liberia and Côte d'Ivoire, and lowland rainforest and forest–savanna mosaic in Senegal and Guinea. On Mt Nimba (Liberia, Guinea), found in montane grasslands below 1400 m (Brosset 1984) and, at Makeni (Sierra Leone), recorded from 'degraded landscape with small relict patches of forest' (Rosevear

*Rhinolophus guineensis*

1965). Local presence and abundance probably determined by availability of suitable day-roosts.

Abundance Usually captured in small numbers in its day-roosts or with mist-nets. Apparently comparatively rare, although 38 individuals were collected during Mar 1990 near Ziggida in the Wonegizi Mts, Liberia (AMNH).

Remarks Day-roosts most often reported are caves and artificial substitutes such as mines (Eisentraut & Knorr 1957, Brosset 1984). Two individuals were found in the hollow trunk of a tree (Böhme & Hutterer 1978). Roosts are regularly shared with other bats including *Lissonycteris angolensis smithii*, *Nycteris macrotis*, *N. gambiensis*, *Rhinolophus simulator alticolus*, *R. denti knorri*, *R. hillorum*, *R. fumigatus*

diversus, *R. maclaudi*, *Hipposideros jonesi* and *H. ruber*. During the day at ca. 1400 m, *R. guineensis* and *R. hillorum* were torpid in their roosts while *R. simulator alticolus* was active (Brosset 1984). Echolocation call-shape FM/CF/FM; CF-frequency 85 kHz (significantly lower than in *R. landeri*; Fahr & Ebigo 2003). Reproduction: no conclusive information.

Conservation IUCN Category: Vulnerable.

Only 15 localities known; distribution small and patchy. Population size probably small; population trend not known but decline inferred because of loss and degradation of habitat. Dependent on caves; colonies small; hence potentially also threatened by exploitation as bushmeat. Ongoing and planned large-scale mining poses special threat in several areas (Fahr & Ebigo 2003).

Rhinolophus hildebrandtii HILDEBRANDT'S HORSESHOE BAT

Fr. Rhinolophe d'Hildebrandt; Ger. Hildebrandts Hufeisennase

Rhinolophus hildebrandtii Peters, 1878. Monatsber. K. Preuss. Akad. Wiss. Berlin 1878: 195. Ndi, Taita Hills, Kenya.

Taxonomy Species-group: *fumigatus*. Synonyms: none. The identities of the large horseshoe bats that are currently called *R. hildebrandtii* in Zambia, Malawi and Zimbabwe are under review. In Zimbabwe, these bats separate into two groups, which differ in their bacular morphology and echolocation. Possibly the smaller form represents *eloquens* (F. P. D. Cotterill, M. Happold & P. J. Taylor unpubl.). Sometimes spelled *hildebranti* and *hildebrandti*, but *hildebrandtii* is the original and correct spelling. Chromosomes (Zimbabwe, South Africa): 2n = 58; aFN = 62. X = large subtelocentric, Y = small metacentric (Rautenbach 1986).

Description Medium-sized microbat with noseleaf (posterior component subtriangular with erect tip); large for an African

rhinolophid; anterior upper premolar displaced labially or absent; connecting process rounded; lancet subtriangular; sella hairy and parallel-sided; no axillary tufts; FA: 60–67 mm. Not easily distinguished from *R. eloquens*. Sexes similar. Pelage soft, dense, fluffy; mid-dorsal hairs 11–13 mm. Dorsal pelage grey to greyish-brown; hairs grey to greyish-brown, darker at tip. Ventral pelage slightly paler than dorsal. No orange-phase. No axillary tufts on adult ♂♂. Ears comparatively and relatively medium-long (26–36 mm, 48 [44–52]% of FA). Noseleaf with lancet long, subtriangular, sides straight or slightly concave; tip rounded. Connecting process rounded, not higher than sella. Sella liberally covered with longish hairs, sides concave near base, parallel above (Figure 60c), top broad and rounded. Horseshoe broad

(11.0–15.0 mm), covering muzzle; lateral leaflets present; median emargination is a deep notch. Lower lip with one groove. Wings and interfemoral membrane dark greyish-brown. First phalanx of fourth finger relatively long (26.5 [24–29]% of fourth metacarpal, $n = 42$). Tibia 44.2 (42–46)% of FA, $n = 116$. Baculum trumpet-shaped with cylindrical shaft, length >3 mm.

Skull robust and comparatively long (GLS: 27.3 [25.0–29.7] mm); zygomatic arches sturdy; zygomatic width much greater than mastoid width. Nasal swellings relatively high, longer than they are broad. Frontal depression deep; supraorbital ridges pronounced. Sagittal crest well developed anteriorly and to ca. half-way across parietals. Palatal bridge of medium to long relative length (32–38% of $C-M^3$; Csorba *et al.* 2003). Anterior upper premolar very small and fully displaced labially or absent; canine and posterior premolar in contact or nearly so. Middle lower premolar apparently always absent; anterior and posterior lower premolars in contact. Dental formula usually $^{1123}/_{2123} = 30$ or $^{1113}/_{2123} = 28$. Further anatomical information in Pearl (1994).

Geographic Variation None recorded.

Similar Species Only two other *Rhinolophus* in Africa have the following combination of characters: anterior upper premolar displaced labially or absent; connecting process rounded and lower than the sella; sella hairy; horseshoe usually broader than 10 mm and as broad as the muzzle or almost so (Table 14, p. 304):

Rhinolophus fumigatus. Smaller (FA: 47–60 mm; Tib: 19–24; CrnC: 22.7 [21.6–24.3] mm). Anterior median nasal swellings broader than they are long.

R. eloquens. Usually smaller (FA: 58 [53–63] mm, Tib: 22–25 mm, CrnC: 25.4 [24.8–26.2] mm). Baculum shorter (<3.0 mm).

Distribution Endemic to Africa. Known mainly from the Somalia–Masai Bushland, Afromontane–Afroalpine, Coastal Forest Mosaic and Zambezian Woodland BZs and from the Eastern Rainforest–Savanna Mosaics. Recorded from Ethiopia and S Sudan to N South Africa (Hayman & Hill 1971, Koopman 1975, 1993, Smithers & Lobão Tello 1976, Aggundey & Schlitter 1986, Cockle *et al.* 1998, Csorba *et al.* 2003). Not recorded from Angola (Crawford-Cabral 1986), but likely to occur in the E and S of that country. A specimen from Kagora in Nigeria, identified as *R. macclaudi* by M. Gartshore (in Happold 1987), has been re-identified as *R. hildebrandtii* by J. Eger (ROM), but this record is very isolated and deserves further investigation. The records from Uganda are considered to represent *R. eloquens* by Thorn & Kerbis Peterhans (2009).

Habitat Recorded from both semi-arid and mesic woodland savannas (including mopane and miombo woodlands) and riverine forests. Also recorded in montane areas in NE Zambia (Ansell & Ansell 1973). Absent from true moist forest, and deserts (Smithers 1983).

Abundance Common in Zimbabwe (F. P. D. Cotterill unpubl.); and locally common in Kenya, as judged from representation in collections (Aggundey & Schlitter 1986). Uncommonly recorded in Malawi (Happold & Happold 1997).

Rhinolophus hildebrandtii

Adaptations Aspect ratio low; wing-loading low; wing-tip rounded. Flight very variable in speed, highly manoeuvrable, looks weak and fluttering. Can take off from ground, and predictably can almost hover. Turns by banking (minimum radius <25 cm), and by stalling-and-twisting and, despite its size, individuals sustained flight within a $1 \times 1 \times 1$ m enclosure for up to four circuits/flight (4 bats, 10 flights each; M. Happold unpubl.). Climbs very short distances by moving hindfeet in alternation (wings not used); uses wings to 'row' itself, very awkwardly, for short distances over horizontal surfaces. Roosts by day in caves, fissures and cavities between and under rocks and boulders, disused mine-adits, abandoned aardvark-burrows and warthog-holes, large hollow trees, in shade under eaves of thatched houses, and in roofs of buildings. Roosts vary from completely dark to merely shaded. Hangs freely from ceilings or hangs in contact with walls. Becomes torpid during day at ambient temperature $21\text{--}24^\circ\text{C}$ (Happold & Happold 1988). Roosts during the night in foliage, usually 2–4 m above ground (Fenton & Rautenbach 1986). Predicted mean maximum urine concentration is medium (3610 mOsmol/kg); captive bats drank regularly every day (Happold & Happold 1988).

Foraging and Food Forages by perch-hunting and by slow-hawking under canopies of woodland or riverine trees (either just above open ground or just above understorey vegetation), close to the outsides of canopies, near and inside buildings, and along corridors of vegetation adjacent to creeks; rarely forages over open ground (Fenton & Rautenbach 1986, M. Happold unpubl.). Slow-hawking flights are characterized by zig-zagging with direction-changes ca. every five seconds; monitored flights lasted up to 53 minutes without an interval for perching (Fenton & Rautenbach 1986). Perch-hunting bats use perches 2–2.5 m above ground; eight observed flights from perches were always towards the ground (but it is not stated if the prey was on the ground or flying); increased repetition-rate of echolocation calls emitted prior to leaving the perch indicates prey was detected from the

perch. Radio-tracked individuals left the day-roost and flew directly for 200–1000 m before beginning to forage; periods of foraging were interspersed with periods of resting at night-roosts; most foraging occurs during first hour or so after emergence from day-roost. Attracted to insects flying around lights; quite often enters houses in search of prey (Smithers 1983). Faecal pellets from Zimbabwe and South Africa contained remains of beetles and moths (and very rarely Diptera) (Fenton *et al.* 1977, Fenton & Rautenbach 1986).

Echolocation Call-shape FM/CF/FM. Maximum energy in second harmonic; four harmonics usually present. In Malawi, CF-frequency 35–38 kHz (1 ♀ 7 ♂ hand-held, 1 ♂ released); maximum variation by a hand-held individual was 1 kHz; call-duration variable, up to 84 ms (M. Happold unpubl.). In Zimbabwe, CF-frequency 37 kHz (one bat, flying in open; Fenton & Bell 1981); 37.6 kHz (F. P. D. Cotterill & P. J. Taylor unpubl.). In South Africa, CF-frequency ca. 40 kHz (Aldridge & Rautenbach 1987). Bats, identified as *R. hildebrandtii*, which emitted CF-frequencies of 47–48 kHz (Malawi; M. Happold unpubl.) and 46 kHz (Zimbabwe; Fenton & Bell 1981) probably represent *R. eloquens* or a closely related form (see profile *R. eloquens*). The acoustics of the vocal tract, and the role of the tracheal chambers and nasal cavities, of bats from Zimbabwe identified as *R. hildebrandtii* (but with CF-frequency ca. 48 kHz therefore probably not this species), were investigated by Suthers *et al.* (1988) and Hartley & Suthers (1988) (see Family Rhinolophidae).

Social and Reproductive Behaviour Roosts singly, in small groups, or in clusters of up to ca. 50 individuals in caves containing several hundreds (Smithers 1983). Individuals in clusters hang apart, usually evenly separated from neighbours. All but three members of a group of 28 adults roosted in the same hollow tree for at least 21 consecutive days (Fenton & Rautenbach 1986). Establishes maternity roosts where each mother hangs separately from other mothers, with her neonate fastened to the pubic nipples. The foraging areas of radio-tracked bats from one day-roost overlapped with those of individuals from other roosts; no agonistic or territorial interactions were observed (Fenton & Rautenbach 1986).

Reproduction and Population Structure Litter-size (Zimbabwe): one (n = 5). Each of 12 ♀♀ had one neonate, which is further evidence that the litter-size is normally one. At 18° 18' S in C Zimbabwe,

the reproductive chronology is restricted seasonal monoestry, with conception and implantation inferred to occur in Jul, births at end of Oct, and lactation for more than three months (Cotterill 1998). Foetuses at limb-bud stage seen in late Aug. Juveniles volant when ca. ten weeks old. At 12° 47' S (Luangwa Valley, Zambia), two juveniles (incisors just erupting) were recorded in mid-Jun (no data for other months; Ansell 1967): this is unexpected in view of the Zimbabwe chronology, but possibly the date of this observation is incorrect.

Predators, Parasites and Diseases Bats leaving one day-roost in a hollow tree in South Africa were pursued by two Barn Owls *Tyto alba* (Fenton & Rautenbach 1986). Ectoparasites recorded by Anciaux de Faveaux (1984) include a bed-bug *Afrocinex leleupi* (Cimicidae), another bug *Adroctenes horvathi* (Polychtenidae); 15 species of bat-flies (Nycteribiidae, Streblidae); five species of mites (Ixodidae, Spinturnicidae, Trombiculidae, Chirodiscidae), but the hosts of at least some of these are *R. eloquens*.

Conservation IUCN Category: Least Concern.

Rhinolophus hilli HILL'S HORSESHOE BAT

Fr. Rhinolophe de Hill; Ger. Hills Hufeisennase

Rhinolophus hilli Aellen, 1973. Period. Biol. Zagreb 75: 101. Uwinka, 2512 m, Parc National de Nyungwe, Préfecture de Cyangugu, Rwanda.

Taxonomy Species-group: *maclaudi* (Fahr *et al.* 2002). Synonyms: none. Smith & Hood (1980) synonymized *R. hilli* with *R. ruwenzorii* and classified the latter taxon as a subspecies of *R. maclaudi*. Csorba *et al.* (2003) considered *R. hilli* to be a subspecies of *R. ruwenzorii*. Fahr *et al.* (2002) showed that both *R. ruwenzorii* and *R. hilli* are clearly differentiated from *R. maclaudi* and re-instated their status as distinct species. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); large for an African rhinolophid (FA: ca. 54 mm); anterior upper premolar displaced labially; lancet subtriangular; connecting process greatly reduced, very low and concave; sella upright with concave sides and broadened tip and greatly enlarged basal lobes; horseshoe with lateral leaflets and deep median emargination; no axillary tufts.

Sexual dimorphism: no information. Pelage soft, woolly; mid-dorsal hairs 13–15 mm. Dorsal and ventral pelage dark brown. Orange-phase: not yet reported. No axillary tufts on adult ♂♂. Ears comparatively and relatively of medium length (29 mm, 53% of FA), pointed, each with nine internal folds; antitragus very large. Noseleaf with lancet subtriangular, height of lancet conspicuously exceeding height of sella (cf. *R. ruwenzorii*). Connecting process greatly reduced, low and concave, leaving a deep emargination between sella and lancet (Figure 59n). Sella naked, upright and more or less parallel to lancet (i.e. not inclined forward), sides concave, top distinctly broadened and rounded (spoon-shaped); narial lobes at base of sella greatly enlarged, forming an almost circular cup. Nostrils bordered by semi-circular, conspicuously raised rims that are parallel to the inner cup (therefore not reaching anterior margin of horseshoe). Horseshoe of medium breadth (12.0 mm); covering muzzle; lateral leaflets present; median emargination conspicuous. Lower lip with a well-defined median groove and two indistinct lateral grooves. Wings and interfemoral membranes dark grey. First phalanx of fourth finger relatively long (27% of fourth metacarpal). Tibia ca. 24 mm, 47% of FA.

Skull large and slender; zygomatic arches broad but comparatively weak, zygomatic width slightly less than mastoid width. Rostrum robust; rostral emargination squarish; premaxillae narrow. Nasal swellings high-domed; chambers (viewed dorsally) roughly circular (posterior indentation weak). Frontal depression very deep. Braincase (viewed dorsally) not conspicuously constricted behind mastoid process, but rather evenly rounded; (viewed laterally) the highest point is clearly behind the glenoid process (cf. *R. macclaudi*). Sagittal crest moderate anteriorly, poorly developed posteriorly. Infraorbital bridge very short and stout. Interpterygoid groove very deep. Anterior upper premolar small, clearly displaced labially; canine and posterior premolar almost in contact. Middle lower premolar small, slightly to clearly displaced labially; distance between anterior and posterior lower premolars variable. Lower molars comparatively large (cf. other species in *R. macclaudi* group). Dental formula $\frac{1123}{2133} = 32$. For detailed comparison of *R. hilli* with other species in *R. macclaudi* group, see Fahr *et al.* (2002).

Geographic Variation No information but, based on small distribution, probably negligible.

Similar Species Three other *Rhinolophus* in Africa have a greatly reduced, low and concave connecting process (Table 14, p. 304):

Rhinolophus ruwenzorii. Larger (FA: 55–62 mm, CrnC: 23.7–25.6 mm, GWS: 11.2–12.3 mm, C–M³: 8.2–8.9 mm). Height of lancet only moderately exceeding height of sella. Skull with braincase constricted behind mastoid process; infraorbital bridge longer and more slender; lower molars comparatively small. Nearly sympatric.

R. macclaudi. Larger (FA: 64–69 mm, CrnC: 29.0–30.1 mm, C–M³: 10.5–10.8 mm). Ears with 10–12 internal folds. Sella inclined forward. Horseshoe broader (15–16 mm), no lateral leaflets, median emargination small or absent, rims around nostrils more or less parallel. Skull with highest point at height of glenoid process; zygomatic width usually > mastoid width; infraorbital bridge much longer and slender. West Africa.

R. ziama. Larger (FA: 60 mm, CrnC: 26.1, 26.2 mm, C–M³: 8.9, 9.0 mm). Ears with 11, 12 internal folds. Sella inclined forward, sides parallel. Horseshoe narrower (11.5, 11.6 mm), no lateral leaflets, median emargination inconspicuous or absent, nostrils bordered laterally by more or less straight and parallel rims. Skull with zygomatic width ≥ mastoid width; infraorbital bridge longer and more slender. West Africa.

Distribution Endemic to Africa and only known from an extremely small area in the Afromontane–Afroalpine BZ flanking the Albertine Rift Valley. Known from only two localities in SW Rwanda (Uwinka and Ruta Bansugera, ca. 8 km apart, in Nyungwe N. P.). The distribution of the *Rhinolophus macclaudi* species-group is very disjunct and resembles that of the otter-shrews of the genus *Micropotamogale* (see species profile for *R. macclaudi*).

Habitat Montane forest, between 1750 and 2512 m.

Abundance Uncertain; apparently very localized and rare.

Remarks The holotype was mist-netted (Aellen 1973) and the day-roosts are not known. The echolocation call-shape is probably FM/CF/FM (as in other species of *Rhinolophus*) and, based on the comparatively large size of this bat, the CF-frequency is likely to be rather low for a *Rhinolophus*. The holotype is a ♀ that was pregnant with a 15 mm embryo in late Aug (Aellen 1973).

Conservation IUCN Category: Critically Endangered.

Distribution extremely small: known from only two specimens collected in 1964 and 1981 within Nyungwe N. P. Surrounding region seriously affected by civil wars; rural population density amongst highest in Africa. Surveys in region of Albertine Rift have not found this species elsewhere. Considered seriously threatened by destruction of its habitat and roosts, and by direct exploitation in its roosts.

Key References Aellen 1973; Fahr *et al.* 2002; Smith & Hood 1980.**Jakob Fahr*****Rhinolophus hillorum* UPLAND HORSESHOE BAT**

Fr. Rhinolophe des collines; Ger. Hochland-Hufeisennase

Rhinolophus hillorum Koopman, 1989. Amer. Mus. Novit. 2946: 4. John Hegbe Farm, near Zozoma, 2 miles SW Voinjama, Lofa County, NW Liberia.**Taxonomy** Originally *Rhinolophus clivosus hillorum*. Species-group: *ferrumequinum*. Proposed as a subspecies of *Rhinolophus clivosus* by Hill (1968, 1982a) and described as such by Koopman (1989) but elevated to species rank by Cotterill (2002a). Synonyms: none. Chromosome number: not known.**Description** Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar absent; connecting process high but rounded; lancet short, mostly narrow and almost parallel-sided; sella parallel-sided; no axillary tufts. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs ca. 10 mm. Dorsal pelage medium brown to greyish-brown. Ventral pelage paler. Orange-phase not yet reported. No axillary tufts on adult ♂♂. Ears comparatively and relatively short (21–24 mm, 40.7 [37–44]% of FA); each with 11–12 internal folds. Noseleaf with lancet short and, except at base, very narrow and almost parallel-sided; tip hairy and slightly rounded (Figure 61f). Connecting process narrow and high but rounded, ellipsoid in profile and liberally furnished with hairs, much higher than sella. Sella naked, almost parallel-sided, diverging slightly towards the rounded top. Horseshoe narrow (8.4–9.1 mm); not completely covering muzzle; no lateral leaflets; median emargination distinct. Lower lip with one groove. Wings and interfemoral membrane blackish-brown. First phalanx of fourth finger relatively long (28.2 [27–31]% of fourth metacarpal, n = 10). Tibia 42.8 (41–44)% of FA, n = 10. Baculum trumpet-shaped, shaft dorsoventrally flattened, length 2.9–3.1 mm, n = 2 (Cotterill 2002a).Skull very robust; zygomatic arches thick and broad; zygomatic width much greater than mastoid width. Rostrum very broad. Nasal swellings very low, frontal depression very shallow. According to Csorba *et al.* (2003), supraorbital crests ill-defined. Sagittal crest anteriorly well developed, posteriorly moderately developed. Dentition robust. Anterior upper premolar absent; canine and posterior premolar in contact. Middle lower premolar absent; anterior and posterior lower premolars in contact. Anterior lower premolar half to two-thirds of the height, and half the crown area, of the posterior premolar. Dental formula $^{1113}/_{2123} = 28$.**Geographic Variation** Quite uniform throughout geographic range but data are limited. A specimen from Lotti Forest, Sudan, which perhaps represents *R. hillorum* (see Distribution), is somewhat smaller than other specimens (FA: 53 mm, CrnC: 23.0 mm, GWS: 12.4 mm, C–M³: 8.9 mm).**Similar Species** Only two other *Rhinolophus* occurring south of the Sahara and north of the Equator have the following combination of characters: anterior upper premolar fully displaced labially or absent; connecting process rounded; sella naked (or with sparse short hairs only) (Table 14, p. 304):*Rhinolophus clivosus*. Connecting process lower and broader in profile. Skull smaller and less robust (CrnC: 18.1–22.8 mm); dentition weaker, C–M³: 6.7–8.9 mm. Anterior upper premolar usually present. Not known in West Africa.*R. deckenii*. Horseshoe broader (9.1–11.5 mm). Skull with nasal swellings moderately high. Frontal depression moderately deep; supraorbital ridges prominent. Anterior upper premolar present or absent; canine and posterior premolar usually separated by narrow gap. East Africa.**Distribution** Endemic to Africa. Known only from three small areas within the Rainforest BZ (Western and West Central Regions) and Afromontane–Afroalpine BZ, and perhaps from one locality in the Eastern Rainforest–Savanna Mosaic. Recorded from 12 localities in Guinea, Liberia, Nigeria, Cameroon and possibly Sudan. Records from Mt Nimba, Guinea (MNHN, published as *R. fumigatus* by Brosset 1984) and from R. Peblei, Liberia (IRS, tentatively identified as *R. alcyone* by Verschuren 1976) represent *R. hillorum* (Fahr *et al.* 2006). Specimens from Tokadeh, Mt Nimba (BMNH) were erroneously listed by Csorba *et al.* (2003) from both Guinea and Liberia; Tokadeh is on the Liberian side of Mt Nimba. A record from Sapoba F. R., Nigeria (M. E. Gartshore in Fedden & Macleod 1986, Cotterill 2002a), is unusual because the locality is situated in lowland rainforest and therefore this specimen should be re-examined. A specimen from Lotti Forest in the Imatong Mts, Sudan (FMNH 67500, published as *R. clivosus keniensis* by Koopman

1975) has characters that indicate it might be referable to *R. hillorum* but the specimen needs re-examination.

Habitat Found in montane forests in the highlands of SE Guinea–NW Liberia and the Cameroon Highlands, and in lowland rainforests and coastal forests in the immediate vicinity of hilly or mountainous landscapes. Found up to 1400 m on Mt Nimba, up to 1950 m on Mt Kupé, Cameroon, and at 1800 m at L. Manenguba, Cameroon. The vegetation has been described as montane grassland (Brosset 1984), montane forest (Fedden & Macleod 1986), dense rainforest (Verschuren 1976), secondary forest with surrounding primary forest (Wolton *et al.* 1982) and gallery forest amidst savanna at the foot of a mountain. The specimen from Lotti Forest, Sudan, was taken in East African Montane Forest at an altitude of ca. 1500 m.

Abundance No detailed information but apparently very localized and rare.

Adaptations Has been recorded roosting by day in caves and artificial equivalents such as mines and bridges (Verschuren 1976, Brosset 1984, Fahr *et al.* 2006). Has been found sharing roosts with *Lissonycteris angolensis smithii*, *Rhinolophus simulator alticolus* and *R. guineensis* (Brosset 1984, as *R. fumigatus*). During the day at ca. 1400 m, *R. hillorum* and *R. guineensis* were torpid in their roosts while *R. simulator alticolus* was active (Brosset 1984).

Foraging and Food No information. Based on body size, probably forages, at least some of the time, by perch-hunting. The powerful skull and teeth suggest that this bat can feed on relatively large and hard-shelled insects.

Echolocation No information.

Social and Reproductive Behaviour There are three reports of these bats roosting in small groups. In Diécké Forest, Guinea, two colonies roosted under small concrete bridges; one colony comprised four ♂♂ and one ♀, and the other comprised one ♂ and three ♀♀ (Fahr *et al.* 2006). One specimen in Liberia was taken from a colony of 10 individuals (sexes not recorded) (Verschuren 1976).

Reproduction and Population Structure Litter-size: one ($n = 1$). Reproductive chronology not known. A ♀ from 07° 29' N (R. Peblei, Liberia) was pregnant in late Jan (Verschuren 1976).

Predators, Parasites and Diseases Ectoparasites include bat-flies *Brachytarsina africana* (Diptera: Streblidae) and a species of the *Raymondia intermedia*-group (Diptera: Streblidae) (Wolton *et al.* 1982).

Conservation IUCN Category: Near Threatened.

Close to qualifying for Vulnerable. Distribution small and disjunct

Rhinolophus hillorum

(five locations). Population size low; trend inferred to be declining as result of deforestation of montane forest within area of occupancy. Small colonies roosting in caves are potentially threatened by exploitation for bushmeat. Populations in the highlands of SE Guinea–NE Liberia are particularly at risk from on-going and planned large-scale mining (Fahr & Ebigo 2003).

Jakob Fahr

Rhinolophus hipposideros LESSER HORSESHOE BAT

Fr. Petit rhinolophe; Ger. Kleine Hufeisennase

Rhinolophus hipposideros (Bechstein, 1800). In: Pennant, Allgemeine Uebers. Vierfüß. Thiere 2: 629. France.

Taxonomy Originally *Noctilio hipposideros*. Species-group: *hipposideros*. Synonyms in Africa: *escalerae*, *minimus* (extraliminally 21 others listed by Simmons [2005]). Subspecies: controversial (see Geographic Variation). Chromosome number (Europe and Asia): $2n = 54, 56, 58, 62$ (Zima *et al.* 1992, Horáček & Zima 1996, Benda & Horáček 1998). This is the only rhinolophid in which chromosomal polymorphism has been reported. However, the older 54 karyotype should be re-examined, and the 62 karyotype probably represents another species (Horáček *et al.* 2000). There are no data from Africa. In specimens from Europe and Asia, 4–10 metacentric and 44–52 acrocentric chromosomes are reported, X is metacentric or acrocentric, Y acrocentric or dot-like (Zima *et al.* 1992, Horáček & Zima 1996, Benda & Horáček 1998).

Description Very small microbat with noseleaf (posterior component subtriangular with erect tip); smaller than any other rhinolophid in Africa (FA: 35–40 mm in Africa); anterior upper premolar within toothrow; connecting process very low and either slightly rounded or flat; lancet long and wedge-shaped; sella wedge-shaped and backward-sloping with the top curving forward; no axillary tufts. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs ca. 10 mm. Dorsal pelage greyish-brown to medium brown (dark grey in juveniles); hairs of adults pale beige with greyish-brown or brown tip. Ventral pelage paler or grey to greyish-white. Apparently no orange-phase. No axillary tufts on adult ♂♂. Ears comparatively short (15–17 mm) but of short–medium relative length (mean E ca. 47% of mean FA). Noseleaf with lancet subtriangular with slightly concave sides, tip bluntly pointed. Connecting process low (not rising above sella), slightly rounded (Figure 59m) or sometimes flat. Sella naked, long, narrow, wedge-shaped; top pointed and curves forward and downward. Horseshoe narrow (6.1–7.1 mm in Africa) but almost covering muzzle; no lateral leaflets; median emargination a distinct notch. Wings and interfemoral membrane medium to dark brown. First phalanx of fourth finger relatively long (26.0 [24–28]% of fourth metacarpal, $n = 31$). Tibia 45.4 (41–49)% of FA, $n = 10$.

Skull very delicate; zygomatic arches extremely slender; zygomatic width slightly greater or almost equal to mastoid width. Nasal swellings of medium relative height. Frontal depression shallow, supraorbital ridges weak. Sagittal crest low and extending part-way across parietals. Palatal bridge (African specimens) relatively short to medium (29–33% of $C-M^3$; G. Csorba pers. comm.). Anterior upper premolar relatively large (reaching one-third height of canine), within toothrow; canine and posterior premolar well separated. Middle lower premolar very small, usually fully displaced labially; anterior and posterior lower premolars in contact or nearly so. Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation Controversial. Six subspecies are currently recognized by Csorba *et al.* (2003) and Simmons (2005), of which two occur in Africa:

R. h. escalerae: NW Africa. Considered subspecifically distinct on basis of size and also the narrowness of the bar between the infraorbital foramen and the orbit (Gaisler 1983, Kowalski & Rzebiak-Kowalska 1991, Steiner & Gaisler 1994). FA: 35.8 (35–38) mm, $n = 9$.

R. h. minimus. Southern Europe to eastern end of Mediterranean, including several islands, and southwards to Sudan, Ethiopia and SW Arabia. Possibly represents a distinct species (see Zagorodniuk 1999). FA: 37.7 (36–40) mm, $n = 10$.

Extraliminally: *majori* (Corsica), *minutus* (Britain and Ireland), *hipposideros* (continental Europe to eastern end of Black Sea), *midas* (Transcaucasia and Iraq to Kazakhstan and Kashmir). In contrast, only *hipposideros* and *midas* have been recognized by majority of authors in the past (Horáček *et al.* 2000). Aulagnier & Thévenot (1986) included both *minimus* and *escalerae* in the nominate subspecies.

Similar Species No other *Rhinolophus* in Africa is so small, and none has the combination of a connecting process that is very low and either slightly rounded or flat and a sella that is wedge-shaped and backward-sloping with the top curving forward (Table 14, p. 304).

Distribution In Africa, recorded from almost all of the Mediterranean Coastal and Afromontane–Afroalpine BZs in NW Africa (Aellen & Strinati 1969, Aulagnier & Thévenot 1986, Kowalski & Rzebiak-Kowalska 1991), and from the Afromontane–Afroalpine BZ of the Ethiopian Highlands and adjacent Somalia–Masai Bushland BZ in Sudan, Ethiopia, Eritrea and Djibouti (Largen *et al.* 1974, Koopman

*Rhinolophus hipposideros*

1975, Pearch *et al.* 2001). Also one record from the Sahara Arid BZ in Sinai (Egypt) (Qumsiyeh 1985). Not known in Libya. In Morocco, recorded from the northern region south to Anti-Atlas and the pre-Saharan region (29°N); in Algeria from the coast to the southern limit of Saharan Atlas (33°N), and in N Tunisia to Kasserine (35°N) (Aellen & Strinati 1969, Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991). Extraliminally: Ireland to Tajikistan, Kashmir and Arabian Peninsula (see Geographic Variation).

Habitat In NW Africa, this cave-roosting species seems to be rare and its foraging habitats are little known. In Algeria, recorded from sea level to ca. 1500 m; three ♂♂ mist-netted in a bushy forest with a permanent stream (Sebdour, Tlemcen Mts), one ♀ mist-netted over water in a desert environment (Brezina, Saharan Atlas [Gaisler & Kowalski 1986, Kowalski & Rzebik-Kowalska 1991]). One specimen was taken beside a lake in an area of grassland, thorn scrub, volcanic rubble and lava blister caves, at ca. 1000 m, in Awash N. P. (Hill & Morris 1971).

Abundance Common in N Morocco but rare in Algeria and Tunisia, even in coastal areas. Probably rare in Sudan, Ethiopia and Eritrea.

Adaptations Aspect ratio very low; wing-loading very low; wing-tip especially short and rounded (Norberg & Rayner 1987). Flight slow (possibly with some short bursts of speed), fluttering and butterfly-like with intermittent gliding; manoeuvrable. Can hover. Day-roosts in Africa include both natural and man-made underground spaces such as caves; individuals hang from ceilings or walls; when torpid and hibernating, they wrap themselves completely in the wing-membranes and draw close to the substrate by bending the legs. In winter in Algeria, they hibernate in the coolest places, usually close to openings (Kowalski *et al.* 1986); extraliminally, temperatures in hibernacula are 6–9 °C and humidity is high (Schober & Grimmberger 1989).

Foraging and Food No information for African populations except that three foraging ♂♂ were mist-netted in bushy areas and one ♀ above water in a desert environment in Algeria (Gaisler & Kowalski 1986, Kowalski & Rzebik-Kowalska 1991), and one individual was reported flying low over the muddy shore of a lake in Ethiopia (Hill & Morris 1971). In England and Eire, bats were observed foraging by gleaning (they usually picked non-volant prey [including larvae] from stones, rocks and vegetation without landing but sometimes pounced on prey on the ground) and by slow-hawking; not known to forage by fly-catching (Jones & Rayner 1989a). Foraged close to vegetation, either patrolling edges of river banks close to riverine vegetation, or close to walls. Some individuals regularly patrolled an ivy-covered bridge when ivy flowers were attracting moths. Apparently patrols well-defined beats. Foraging is strictly nocturnal; sometimes reported to continue for at least five hours after sunset. In Europe, diet is mainly small Lepidoptera and Diptera (Nematocera), and less often Neuroptera, Trichoptera, Coleoptera and Araneae.

Echolocation No data for African populations. In England and Europe, call-shape usually FM/CF/FM with the terminal FM component greater in bandwidth; some CF and CF/FM calls

are emitted during slow-hawking (Jones & Rayner 1989a). CF-frequency 105–113 kHz; call-duration 20–30 ms; maximum energy in second harmonic (but some in first harmonic); average terminal FM bandwidth 29.1 kHz suggesting *R. hipposideros* relies particularly heavily on FM information (Jones & Rayner 1989a). For hand-held bats, the CF-frequencies of calls emitted by bats more than one year old were higher than those emitted by younger bats, and ♀♀ emit higher frequencies than ♂♂ (Jones *et al.* 1992).

Social and Reproductive Behaviour In North Africa in winter, single individuals, mostly ♂♂, were sporadically seen roosting in caves (Kowalski *et al.* 1986); no other information. Extraliminally (Europe), during winter, hibernates singly or in colonies of up to 500 individuals, which hang apart, 25–50 cm from their neighbours (Macdonald & Barrett 1993). In summer, ♀♀ form maternity colonies of 10–800 individuals; immature ♂♂ sometimes present; ♀♀ hang apart except when heavily pregnant in cool weather, or when huddling with their young. Audible (to humans) vocalizations at roosts include chirping. Mating often takes place in autumn; preceded by chasing; ♂ hangs behind and over ♀ during brief copulation; sometimes copulates in hibernacula.

Reproduction and Population Structure Litter-size: no data for Africa. In Iran, ca. 65% of ♀♀ bear singletons, and 35% bear twins (DeBlase 1980 in Csorba *et al.* 2003); in Europe, litter-size is one. Reproductive chronology in Africa not known. In Europe, it is restricted seasonal monoestry with mating in autumn (Sep–Nov) or in hibernacula during winter; sperm-storage by ♀♀ until Mar–Apr when ovulation and fertilization occur; births in summer (mid-Jun to early Jul); lactation for 4–5 weeks (Gaisler 1966, Macdonald & Barrett 1993). A ♀ with vaginal plug was recorded in Jan at Sig, NW Algeria (Kowalski *et al.* 1986). Extraliminally, ♀♀ reach sexual maturity in first year, but most give birth for first time when two years old. Maximum life-span: 21 years 3 months.

Predators, Parasites and Diseases Preyed on, rarely, by Barn Owls *Tyto alba* (Cabrera 1932 in Aulagnier & Thévenot 1987). Ectoparasites include a bat-fly *Phthiridium biarticulatum* (Diptera: Nycteribiidae) for which *R. hipposideros* is the principal host (Corbet & Harris 1991).

Conservation IUCN Category: Least Concern (assessed from extralimital as well as African data).

Rhinolophus landeri LANDER'S HORSESHOE BAT

Fr. Rhinolophe de Lander; Ger. Landers Hufeisennase

Rhinolophus landeri Martin, 1838. Proc. Zool. Soc. Lond. 1837: 101 [publ. 1838]. Bioko I., Equatorial Guinea.

Taxonomy Species-group: *landeri*. Synonyms: *angolensis*, *axillaris*, *dobsoni*, *lobatus*. Subspecies: three. Chromosome number (South Africa): 2n = 58; aFN = 60. Two pairs biarmed chromosomes and 26 pairs acrocentric chromosomes. X = large submetacentric; Y = no data (Rautenbach 1986).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); small for an African rhinolophid; anterior upper premolar within toothrow; connecting process triangular; lancet hastate; sella parallel-sided; axillary tufts in adult ♂♂ reddish or reddish-brown; first phalanx of fourth finger relatively short; tibia 17–21 mm. Sexes similar. Pelage dense, soft, fluffy; mid-dorsal hairs 8–9 mm. Dorsal pelage greyish-fawn to brownish-grey; hairs pale greyish-fawn or pale brownish-grey with darker tip. Ventral pelage slightly paler. In orange-phase, dorsal pelage golden-brown, orange-cinnamon to bright rusty-red. Adult ♂♂ with reddish or reddish-brown axillary tufts, which are sometimes sticky with yellow secretion. Ears comparatively and relatively short (13–20 mm, 34–42% of FA). Noseleaf with lancet hastate, tip bluntly pointed. Connecting process subtriangular with tip either sharply or bluntly pointed. Sella naked, narrow with slightly concave sides, top broad and rounded. Horseshoe narrow (6.0–8.0 mm) but covering whole

muzzle; no lateral leaflets; median emargination a deep notch. Lower lip with a well-defined median groove and two very poorly defined lateral grooves. Wings and interfemoral membrane dark greyish-brown to blackish-brown (grey-phase) or brown (orange-phase). First phalanx of fourth finger relatively short (21.0 [19–23]% of fourth metacarpal, n = 52). Tibia 42.4 (38–45)% of FA, n = 18.

Skull of medium build; zygomatic arches of moderate breadth; zygomatic width slightly greater than mastoid width. Nasal swellings of medium relative height. Frontal depression usually shallow (Csorba *et al.* 2003). Sagittal crest low to moderately developed anteriorly, absent posteriorly. Palatal bridge 28–37% of C–M³ (Csorba *et al.* 2003). Anterior upper premolar small, within toothrow or only slightly displaced labially; canine and posterior premolar well separated. Molar width less than half width of palate between molars (cf. *R. blasii*). Lower canines not distinctly smaller than upper canines (cf. *R. denti*, *R. simulator*, *R. swinnyi*). Middle lower premolar small, slightly to fully displaced labially; anterior and posterior lower premolars separated by narrow gap or in contact. Anterior lower premolar (*R. l. landeri*) only a little smaller than posterior lower premolar; more than half and usually two-thirds of its height (Kock *et al.* 2002) (cf. *R. guineensis*). Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation Three subspecies are recognized by Koopman (1994):

R. l. landeri: Gambia to Cameroon and south to mouth of Congo R.

R. l. lobatus: Sudan and Ethiopia, and south to former Transvaal; also Zanzibar I.

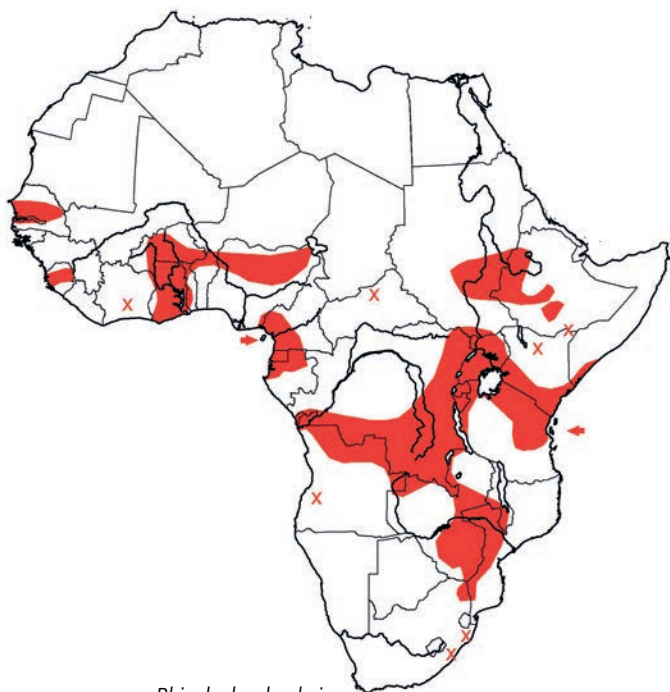

R. l. angolensis: W Angola.

Similar Species Only two other sub-Saharan *Rhinolophus* have the following combination of characters: anterior upper premolar within toothrow; connecting process triangular and pointed; first phalanx of fourth finger relatively short (Table 14, p. 304):

Rhinolophus guineensis. Body measurements usually larger (FA: 44–50 mm [cf. 39–45 in *R. landeri* from West Africa], Tib: 21–22 mm). Skull larger (CrnC: 19.2–20.6 mm [cf. <18.9 in *R. landeri* from West Africa]). Axillary tufts of ♂♂ white. Horseshoe broader (8.3–9.3 mm). Not known to occur east of 07° 30'W.

R. alcyone. Body measurements larger (FA: 48–56 mm, Tib: 21–27 mm). Skull larger (CrnC: 21.0–23.3 mm).

Distribution Endemic to Africa. Found in most sub-Saharan biotic zones, but apparently absent from large areas in each zone. No records

Rhinolophus landeri

from the arid Horn of Africa, nor from the South-West Arid, Highveld and South-West Cape BZs. Recorded (disjunctly) from Gambia and Senegal to Ethiopia, and south to the former Transvaal and KwaZulu-Natal in South Africa. Also Bioko I. A record from Namibia (Slater 1901) represents *R. darlingi*. Mapped from country checklists (see order Chiroptera), other literature and museum records. Subsequently recorded from Liberia (Monadjem & Fahr 2007): not mapped.

Habitat In West Africa, recorded mainly in lowland rainforest and degraded forest (Rosevear 1965). Also recorded in *Isoberlinia* woodland and occasionally in undifferentiated woodland, often near rivers and riverine woodland. Recorded in montane vegetation at 1400 m on Mt Cameroon, Cameroon, and in primary forest at 1000 m on Mt Bintamane, Sierra Leone (Rosevear 1965). Recorded from 515 to 1800 m in Ethiopia (Largen *et al.* 1974), and from sea level to 1981 m on Mt Elgon, in Kenya (Aggundey & Schlitter 1984). In Malawi and southern Africa, recorded mainly in woodland savannas, often near riverine woodland and well-watered areas (R. C. Wood in Kershaw 1922, Smithers 1983). In Zimbabwe, predominantly recorded below 1200 m and apparently absent from miombo and *Baikiaea*-dominated areas (Hutton 1986). Not recorded from arid zones. The presence of suitable day-roosts is possibly more important than vegetation (Smithers 1983).

Abundance No information.

Adaptations Aspect ratio low; wing-loading very low (Aldridge & Rautenbach 1987). Can fly slowly (minimum 3.5 m/s) with bursts of speed. Has great manoeuvrability; can take off from the ground and can hover briefly. By day, hangs freely in caves, caverns in rocky outcrops and piles of boulders, mine-adits, enclosed roofs, wells and other holes in ground, hollow baobabs *Adansonia*, and hangs from thatch inside thatched buildings. Both active and torpid individuals were found in a cave in Cameroon (Eisentraut 1940). In Nigeria, Menzies (1973) observed that young and newly moulted bats were in grey-phase, but became golden in colour later, possibly as result of high concentrations of ammonia (released from guano) in the cave where they roosted.

Foraging and Food Slow-hawking within 2 m of the ground has been observed in rainforest, well after daybreak (T. S. Jones in Grubb *et al.* 1998) and in savanna (O'Shea & Vaughan 1980). There are no records of fly-catching and gleaning, but both are predicted to occur (based on wing morphology). In Zimbabwe, the remains of ca. 66 insects found under a roost included 92% noctuid moths, one butterfly and several Orthoptera (Fenton 1975). In the Sudan, the diet is mainly small beetles (Kock 1969a).

Echolocation Call-shape FM/CF/FM. CF-frequency appears to vary: 101 kHz in Côte d'Ivoire (Fenton & Fullard 1979); 115–122 kHz in Nigeria (Pye & Roberts 1970); 55 kHz (presumably first harmonic) in Kenya (O'Shea & Vaughan 1980); 110 kHz in South Africa (Aldridge & Rautenbach 1987). According to Novick (1958b), 73–84 kHz in DR Congo, but this seems too low for the second harmonic, and too high for the first harmonic, for this species.

Social and Reproductive Behaviour Roosts singly or in groups. Group-size in southern Africa less than 12 (Taylor 2000);

20–50 in DR Congo; ca. 1000 in one cave in Nigeria (Menzies 1973). Individuals hang apart in clusters. In Nigeria, one cave was usually inhabited by both ♂♂ and ♀♀, but ♂♂ left prior to parturition and did not return until young were weaned (Menzies 1973). Often shares day-roosts with other species including *Lissonycteris angolensis*, *Coleura afra*, *Nycteris arge*, *N. macrotis*, *Rhinolophus fumigatus*, *R. simulator*, *Hipposideros cyclops*, *H. abae*, *H. caffer* and *H. jonesi*.

Reproduction and Population Structure Litter-size: one. Reproductive chronology is restricted seasonal monoestry, with delayed implantation in at least one locality. At 10° 20' N (Shagunu, Nigeria), copulation occurs in early dry season (Nov), ovulation in late Nov, implantation (after approximately two months' delayed implantation) in late dry season (early Feb), parturition in early wet season (ca. late Apr), and lactation during wet season (Apr–Jun) (Menzies 1973). Newborn bats may be carried for a short time by their mothers while foraging; young begin to fly when 4–5 weeks old. There is some evidence that ♂♂ and ♀♀ do not breed until their second year. Young are weaned when two months old (Anciaux de Faveaux 1972). Year-round observations have not been made elsewhere, but births have been recorded during the wettest month, in the short wet season (Nov) at 02° 18' S (Masalani, near Kibwezi, Kenya; records Oct–May only) (O'Shea & Vaughan 1980). For other records (inconclusive) see Brown & Dunlop (1997).

Predators, Parasites and Diseases Ectoparasites include a bug *Adroctenes horvathi* (Hemiptera: Polytentidae); fleas *Lagaropsylla setzeri*, *L. idae* (Siphonaptera: Ischnopsyllidae); ten species of bat-flies (Diptera: Nycteribiidae, Streblidae); ten species of mites (Acari: Spinturnicidae, Macronyssidae, Myobiidae, Leeuwenhoekidae, Chirodiscidae) (Anciaux de Faveaux 1984, Brown & Dunlop 1997, Kock *et al.* 1998b).

Conservation IUCN Category: Least Concern.

Meredith Happold

Rhinolophus macclaudi MACCLAUD'S HORSESHOE BAT

Fr. Rhinolophe de Macclaud; Ger. Macclauds Hufeisennase

Rhinolophus macclaudi Pousargues, 1898 [publ. 1897]. Bull. Mus. Natn. Hist. Nat. 3: 358. Conakry I., Guinea.

Taxonomy Species-group: *macclaudi* (Fahr *et al.* 2002). Synonyms: none. Smith & Hood (1980) classified *R. ruwenzorii* (including *R. hilli* as a synonym) as a subspecies of *R. macclaudi*. Fahr *et al.* (2002) showed that both *R. ruwenzorii* and *R. hilli* are clearly differentiated from *R. macclaudi* and re-instated their status as distinct species. Traditionally, *R. macclaudi* was placed in the otherwise Australasian *philippinensis*, *luctus* or *trifolius* species-groups (Andersen 1905c, d, Hill 1942, Aellen 1973, Koopman 1994). In contrast, Laurent (1940, 1941) concluded that *R. macclaudi* is not closely related to any Australasian form but instead represents an archaic African species. A closer affinity with African forms was partly supported by Bogdanowicz (1992) and Bogdanowicz & Owen (1992), who studied the phenetic and phylogenetic relationships of the genus *Rhinolophus*. Recently, Fahr *et al.* (2002) revised the taxa allied to *R. macclaudi* and established the *macclaudi* species-group to comprise *R. macclaudi*, *R. ziama*, *R. ruwenzorii* and *R. hilli*. Chromosome number: not known.

Description Medium-sized microbat with noseleaf (posterior component subtriangular with erect tip); on average the largest rhinolophid in Africa (FA: 64–69 mm); anterior upper premolar within tooththrow; connecting process greatly reduced, low and concave; lancet subtriangular; sella parallel-sided, inclined forward, with greatly enlarged basal lobes; horseshoe without lateral leaflets, median emargination small or absent. Sexual dimorphism: none apparent. Pelage soft, woolly; mid-dorsal hairs 13–14 mm. Dorsal pelage pale chestnut to greyish-brown; hairs with slightly paler base. Ventral pelage paler than dorsal pelage. Orange-phase: not yet reported. No axillary tufts on adult ♂♂. Ears comparatively and relatively long (40–46 mm, 63.7 [61–70]% of FA, *n* = 6), each with 10–12 internal folds. Noseleaf with lancet subtriangular, tip pointed; height of lancet conspicuously exceeding height of sella. Connecting process greatly reduced, low and concave, leaving a deep emargination between sella and lancet. Sella naked, inclined forward and therefore not parallel to lancet, almost parallel-sided; top not distinctly broadened; narial lobes at base of sella greatly enlarged, forming a roughly heart-shaped corolla-like cup. Nostrils laterally bordered by conspicuously raised, almost straight and more or less parallel rims, which almost reach anterior margin of horseshoe. Horseshoe broad (15.0, 16.0 mm); no lateral leaflets; median emargination very small or absent. Lower lip with one groove. Wings and interfemoral membrane dark grey. First phalanx of fourth finger relatively long (25.6 [25–29]% of fourth metacarpal, *n* = 6). Tibia 28–31 mm, 44.4 (43–46)% of FA, *n* = 6.

Skull large, slender; zygomatic arches broad but comparatively weak, dorsally notched; zygomatic width \geq mastoid width. Rostrum robust; rostral emargination U-shaped; premaxillae broad. Nasal swellings high-domed; chambers (viewed dorsally) roughly heart-shaped (with posterior indentation). Frontal depression very deep. Braincase (viewed dorsally) constricted behind mastoid process; viewed laterally, the highest point is directly above the glenoid process. Sagittal crest moderate anteriorly, low posteriorly. Infraorbital bridge

moderately long and slender. Interpterygoid groove very deep. Palatal bridge relatively long (45–48% of C–M³; Csorba *et al.* 2003). Anterior upper premolar small, within tooththrow or only slightly displaced labially; canine and posterior upper premolar separated. Middle lower premolar small, clearly displaced labially, anterior and posterior lower premolars either in contact or separated; anterior lower premolar ca. half to two-thirds of the height of the posterior premolar. Lower molars medium-sized (cf. *R. hilli* and *R. ruwenzorii*). Dental formula $^{1123}/_{2133} = 32$. For detailed comparison of *R. macclaudi* with other species in *R. macclaudi* group, see Fahr *et al.* (2002).

Geographic Variation None.

Similar Species Three other *Rhinolophus* in Africa have a greatly reduced, low and concave connecting process (Table 14, p. 304):

Rhinolophus ziama. Smaller (FA: 60 mm, CrnC: 26.1, 26.2 mm, C–M³: 8.9, 9.0 mm). Horseshoe narrower (11.5, 11.6 mm). Ears shorter (35, 36 mm). Skull with highest point clearly behind glenoid process; infraorbital bridge longer and more slender. West Africa.

R. ruwenzorii. Smaller (FA: 55–62 mm, CrnC: 23.7–25.6 mm, C–M³: 8.2–8.9 mm). Ears shorter (32–38 mm) with eight internal folds. Sella upright and more or less parallel to lancet. Horseshoe narrower (10.8–12.6 mm); lateral leaflets present, median emargination conspicuous, rims around nostrils semi-circular. Skull with highest point clearly behind glenoid process; zygomatic width < mastoid width; infraorbital bridge stouter and shorter. Mountains flanking Albertine Rift Valley.

R. hilli. Smaller (FA: 54 mm, CrnC: 23.0 mm, C–M³: 7.9, 8.1 mm). Ears with nine internal folds. Sella upright and more or less parallel to lancet. Horseshoe narrower (12 mm), lateral leaflets present, median emargination conspicuous, rims around nostrils semi-circular. Skull with highest point clearly behind glenoid process; zygomatic width < mastoid width; infraorbital bridge much shorter and stouter. Mountains flanking Albertine Rift Valley.

Distribution Endemic to Africa. Only known from ca. 360 km² in the Northern Rainforest–Savanna Mosaic in Guinea. The holotype is supposedly from Conakry I., but all other specimens are from three localities (ca. 150 km away) situated along the lower, SE slopes of the Fouta Djallon highlands between Kindia and Mamou near the border with Sierra Leone. Specimens from Kagoro, C Nigeria (M. E. Gartshore in Happold 1987, Koopman *et al.* 1995), have been re-identified as *R. hildebrandtii* (J. Eger in Fahr *et al.* 2002). Csorba *et al.* (2003) listed two separate localities from Guinea (Nyembaro; Salung Plateau), but these represent the same locality. A record from Liberia (Koopman 1994, Koopman *et al.* 1995, Csorba *et al.* 2003) was re-identified as *R. ziama* (Fahr *et al.* 2002). The distribution pattern of the *R. macclaudi* species-group strikingly resembles that of the otter-shrews *Micropotamogale lamottei* and *M. ruwenzorii* with a remarkable disjunction between the highlands of Guinea, N Liberia and W

Rhinolophus maclaudi

Côte d'Ivoire in the West and the mountains flanking the Albertine Rift Valley in the East. Both the *R. maclaudi* species-group and the two species of *Micropotamogale* apparently have a paramontane distribution (*sensu* Koopman 1983), i.e. their distribution is restricted to mountainous regions although their altitudinal range covers both lower and higher elevations.

Habitat Except for the holotype, all specimens are from a region where the predominant vegetation is bush-tree savanna intersected by forests along rivers and in topographically protected pockets.

Abundance Uncertain but probably extremely localized and rare. Only nine specimens known with gap of 58 years between captures of the holotype (1896) and the next specimen (1954). Not recorded since 1968.

Remarks Most specimens were taken from their day-roosts in caves (Aellen 1956a, Eisentraut & Knorr 1957); one was caught

in a house (Aellen 1973). Day-roosts were shared with small colonies of *Lissonycteris angolensis smithii*, *Nycteris macrotis*, *Rhinolophus guineensis*, *R. fumigatus diversus*, *R. denti knorri* and larger colonies of *Hipposideros ruber* and *H. jonesi* (Eisentraut & Knorr 1957, Fahr *et al.* 2002). Echolocation call-shape likely to be FM/CF/FM (as in other *Rhinolophus*) and, based on the comparatively large size of this bat, the CF-frequency is likely to be rather low for a *Rhinolophus*. Roosts singly or in small groups. Eisentraut & Knorr (1957) reported a group consisting of three ♂♂ and three ♀♀ in one cave, and two individuals (including 1 ♀) in another cave.

Predators, Parasites and Diseases Ectoparasites include some unidentified mites (Acari) (Aellen 1956a).

Conservation IUCN Category: Endangered.

Major threats: occurs in densely populated region affected by continuous destruction of habitat; highly dependent on caves, therefore vulnerable to disturbance at roosts and exploitation as bushmeat. See also Distribution and Abundance.

Rhinolophus maendeleo MAENDELEO HORSESHOE BAT

Fr. Rhinolophe de Maendeleo; Ger. Maendeleo Hufeisennase

Rhinolophus maendeleo Kock, Csorba and Howell, 2000. Senckenbergiana Biol., 80: 234. Amboni Cave Forest, Mkulumuzi R. Gorge, 2.5 km west of Tanga, Tanga District, Tanzania.

Taxonomy Species-group: *adami*, with *R. adami* (Kock *et al.* 2000). Synonyms: none. Its closest known relative appears to be *R. adami*. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar within tooththrow; connecting process rounded and comparatively high; lancet subtriangular with

slightly concave sides; sella with markedly concave sides and top, which is angled obtusely forward; horseshoe breadth 8.2, 8.5 mm. Sexual dimorphism: no information. Dorsal pelage medium brown; hairs medium brown. Ventral pelage beige merging into white on lower abdomen; darker brown collar around lower neck and upper chest. Orange-phase: no information. Axillary tufts: no information. Ears comparatively short (24, 25 mm) but of medium relative length (49–51% of FA), reaching beyond tip of nose when laid forward; tips

bluntly rounded. Noseleaf with lancet subtriangular, sides slightly concave (Figure 61d); tip bluntly pointed (cf. *R. adami*). Connecting process well developed, hairy, smoothly rounded (arched) and high. Sella naked, broad at base, sides markedly concave, top curving obtusely forward. Lobes at base of sella poorly developed but surrounding a well-developed narial cup. Horseshoe narrow (8.2, 8.4 mm) but almost covering muzzle; no lateral leaflets, median emargination well defined. Lower lip with three well-defined grooves. Wings brown; first phalanx of fourth finger of medium relative length (21, 23% of fourth metacarpal). Interfemoral membrane brown. Tibia 38, 40% of FA. Baculum with dorsal and ventral parts of basal cone deeply invaginated so sides of cone form two long wings, ventral invagination less deep; shaft becoming dorsoventrally flattened distally; tip slightly expanded; length 2.66 mm (Kock *et al.* 2000).

Skull narrow; zygomatic width equal to or slightly narrower than mastoid width. Nasal swellings relatively high. Anterior median swellings bulbous, broad and long; posterior swellings less developed (Csorba *et al.* 2003). Frontal depression moderately deep. Sagittal crest low. Infraorbital foramen open, not covered by bony bar (cf. *R. adami*). Palatal bridge 2.70, 2.78 mm, 37, 39% of C–M³. Anterior upper premolar small, within toothrow; canine and posterior premolar well separated. Middle lower premolar small, somewhat displaced labially; anterior and posterior lower premolars separated. Dental formula $^{1123}_{2133} = 32$.

Geographic Variation None recorded.

Similar Species Five other *Rhinolophus* in Africa have the anterior upper premolar in the toothrow and a rounded connecting process:

Rhinolophus adami. Lancet subtriangular with slightly convex sides; connecting process rising well above sella; sella with only slightly concave sides, top of sella curving acutely forward and slightly downward, horseshoe broader (8.5, 9.0 mm). Skull with infraorbital foramen closed by bony bar; palatal bridge 42, 44% of C–M³. Rainforest, Congo.

R. simulator. Ears shorter (18–23 mm). Lancet hastate, horseshoe almost always narrower (6.7–8.3 mm). FA shorter in area of sympatry (42–47 mm).

R. swinyi. Lancet hastate, horseshoe narrower (6.8–7.4 mm). FA shorter (40–44 mm).

R. denti. Horseshoe narrower (6.8–7.5 mm). FA shorter (37–44 mm).

R. capensis. Horseshoe narrower (7.2–8.1 mm). South Africa.

Distribution Known only from three localities in Tanzania: the type locality (Amboni Cave Forest, 05° 5'S, 39° 02'E), Mazumbai F. R. (04° 25'S, 38° 15'E) on the east ridge of West Usambara Mts (Kock *et al.* 2000), and Iringa (07° 48'S, 35° 43'E) (F. P. D. Cotterill pers. comm.). The first two localities are in relict forests in the Coastal Forest Mosaic BZ (and in the Swahili regional centre of endemism of Burgess *et al.* 1998). Iringa is in the Somalia–Masai Bushland BZ.

Habitat Amboni Cave Forest is a coastal forest of 350 ha, altitude 0–80 m, consisting of degraded forest and evergreen thicket in a limestone gorge. Masumbai Forest is a primeval lower montane rainforest of 450 ha, at altitude 1400–1900 m. The unique nature of these forests is described by Sheil (1992). The altitude of Iringa is ca. 1650 m; no other details available.

Abundance No information. Only four specimens known.

Remarks Nothing else is known about this species.

Conservation IUCN Category: Data Deficient.

Distribution, population size and trend not sufficiently known. The coastal forest localities from which this species has been recorded lie wholly within protected areas (Kock *et al.* 2000). Threats facing these forests and their inhabitants are described by Sheil (1992).

Meredith Happold

Rhinolophus maendeleo

Rhinolophus mehelyi MÉHELY'S HORSESHOE BAT

Fr. Rhinolophe de Méhely; Ger. Méhely Hufeisennase

Rhinolophus mehelyi Matschie, 1901. Sitzb. Ges. Naturf. Fr. Berlin, p. 225. Bucharest, Romania.

Taxonomy Species-group: *euryale*. Synonyms: *carpetanus* and, following Cockrum (1976), *tuneti*. Subspecies: uncertain (see Geographic Variation). Chromosome number (Tunisia): $2n = 58$; $aFN = 60$ (Baker *et al.* 1974); 4–8 metacentric and 48–52 acrocentric autosomes, X = large metacentric, Y = small acrocentric. In Romania, $aFN = 64$ (Dulić & Soldatović 1969); in Azerbeidjan, $aFN = 64$ (Zima *et al.* 1992).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium–small for an African rhinolophid; anterior upper premolar somewhat displaced; connecting process triangular; lancet hastate with distal half narrow and almost parallel-sided; sella parallel-sided; first phalanx of fourth finger relatively short, and marked contrast between crown areas of anterior and posterior lower molars (cf. *R. blasii*); usually with dark spectacles around the eyes (cf. *R. euryale*). Not easily distinguished from *R. euryale*. Sexes similar. Pelage soft, dense, velvety; mid-dorsal hairs 8–9 mm. Dorsal pelage greyish-brown; hairs pale greyish-beige with greyish-brown at tip. Face paler, usually with dark brown hairs around eyes creating fairly conspicuous brown ‘spectacles’ (or a patch under each eye). Ventral pelage much paler, almost white to pure white; boundary with dorsal pelage fairly distinct. Apparently no orange-phase. Axillary tufts: no information. Ears comparatively and relatively short (19–23 mm, mean E ca. 42% of mean FA). Noseleaf with lancet hastate, with upper half narrow, almost parallel-sided but tapering slightly; tip bluntly pointed. Sella naked, parallel-sided with top broad, rounded and tilted forward. Connecting process subtriangular. Horseshoe narrow (4.9–7.5 mm), not covering whole muzzle; no lateral leaflets; median emargination slight. Grooves in lower lip: no information. Wings and interfemoral membrane greyish-brown; first phalanx of fourth finger relatively short (21.2 [19–23]% of fourth metacarpal, $n = 24$) and < 50% of second phalanx (cf. most *R. blasii*). Tibia 41.4 (40–44)% of FA ($n = 13$).

Skull of medium build; zygomatic arches slender; zygomatic width invariably greater than mastoid width. Nasal swellings low. Frontal depression shallow to almost flat; supraorbital ridges indistinct. Sagittal crest moderately developed. The bar between the infraorbital foramen and the orbit is narrow, and the infraorbital foramen is large (cf. *R. euryale*). Palatal bridge of medium relative length, 32–33% of $C-M^3$ (Csorba *et al.* 2003). Anterior upper premolar somewhat displaced labially but canine and posterior premolar not in contact. Middle lower premolar minute, fully displaced labially; anterior and posterior lower premolars in contact. Crown area of lower anterior premolar is 50% or less than that of the posterior lower premolar. Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation Controversial. Two subspecies are recognized by Gaisler (1983), Koopman (1994), Csorba *et al.* (2003) and Simmons (2005):

R. m. mehelyi: Europe and W Asia.

R. m. tuneti: North Africa.

However, Aellen & Strinati (1970) and Felten *et al.* (1977) stated that the taxonomic position of *tuneti* cannot be determined. Furthermore, specimens from Morocco, Algeria and Tunisia were not considered to differ from those from elsewhere by Felten *et al.* (1977), Aulagnier & Thévenot (1986) and Kowalski & Rzebik-Kowalska (1991). Here, pending further studies, *tuneti* is not considered to be a valid subspecies.

Similar Species No other *Rhinolophus* in North Africa has a triangular connecting process. Two other rhinolophids in North Africa have pointed connecting processes but, in each of these species, the connecting process rises to a high, narrow, forward-curving horn (Table 14, p. 304):

Rhinolophus euryale. Lancet subtriangular (distal half not tapering to a thin apex). Eyes with faint spectacles; bases of dorsal hairs almost white; ventral pelage never white or almost white. Craniodental characters almost indistinguishable.

R. blasii. Sella wedge-shaped, horseshoe usually broader (7.2–9.0 mm). First phalanx of fourth finger relatively long (24–28% of fourth metacarpal). No marked contrast between crown areas of anterior and posterior lower premolars.

Most specimens of both *euryale* and *blasii* are a little smaller than *mehelyi*.

Distribution In Africa, known from the Mediterranean Coastal and Afromontane–Afroalpine BZs in the Maghreb (NW Africa) and

Rhinolophus mehelyi

from the northern edge of the Sahara Arid BZ in NE Libya (Cyrenaica) and the Nile Delta in NE Egypt. Recorded from N Morocco, Algeria (from coast to Saharan Atlas), N Tunisia, NE Libya (Cyrenaica) and N Egypt as far south as Saqqara (Hanák & Elgadi 1984, Qumsiyeh 1985, Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991, Benda *et al.* 2004d). Extraliminally: Portugal to Caucasus, and Israel, Iran, Iraq and Afghanistan.

Habitat In Africa, this cave-roosting species inhabits regions rich in caves or man-made subterranean shelters. In the supra-Saharan region, has the widest distribution of all horseshoe bats and occurs in various dry Mediterranean habitats of the Maghreb, Cyrenaica and NE Egypt. Found in several places along the Atlantic coast of Morocco but apparently absent from coastal areas with high rainfall, such as the Mediterranean coast of the Algerian Kabylia. In Morocco and Algeria, recorded from sea level to ca. 2000 m in the High and Saharan Atlas (Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991, Benda *et al.* 2004d). In Algeria, netted only once in a rocky ravine at Brezina (Gaisler & Kowalski 1986). Seems to occur in Mediterranean forests, woodlands and montane forests, and sub-Mediterranean semi-desert grassland and shrubland.

Abundance Common in N Morocco and NW Algeria, rare in remainder of geographic range in Africa.

Adaptations Flight slow, very manoeuvrable, with short glides. In Algeria (and elsewhere), roosts by day in caves; hangs from ceilings with body not completely enveloped by the wings. In Arabia, also observed half protruding from cracks and fissures in ceiling of a cave in which the temperature reached maximum of 31.5°C, and humidity was very high (Harrison & Bates 1991). No precise data on hibernation available; in Algerian caves, both active and torpid individuals were observed in winter (Kowalski & Rzebik-Kowalska 1991). At one cave, very fat ♀♀ and ♂♂, which were devoid of fat, roosted in the warm chambers in autumn; in winter they roosted near the entrance (Kowalski *et al.* 1986). Caves are often shared with *R. ferrumequinum*, *Myotis punicus* and/or *Miniopterus schreibersii*; in winter these species roost in inter-specific clusters, but in spring and summer they roost separately (Kowalski *et al.* 1986).

Foraging and Food No information from Africa. Lepidoptera were found in stomachs in Romania (n = 3) (Gaisler 2001c). In Iran, the food of a maternity colony was mainly Lepidoptera (68–97% by volume), followed by Coleoptera (3–29%) and Diptera (0.1–1.3%) (Sharifi & Hemmati 2001).

Echolocation Call shape: FM/CF/FM. CF-frequency (Europe) 109 (105–112) kHz; call-duration 20–30 ms (Heller & von Helversen 1989, Schober & Grimmberger 1989).

Social and Reproductive Behaviour Roosts singly, in groups or in very large colonies; extraliminally up to 3000 in summer and 5000 in winter. A maximum of ca. 1000 was recorded on one occasion at a regularly visited cave at Misserghin (Algeria) (Kowalski *et al.* 1986). Individuals, whether torpid or active, sometimes roost

in contact with their neighbours (unlike other *Rhinolophus* in North Africa), and sometimes hang apart in loose clusters. During winter, ♂♂ and ♀♀ roosted together; in the Misserghin cave, both ♂♂ and ♀♀ continued roosting together during spring, but ♂♂ departed prior to parturition, leaving ♀♀ in what became a maternity colony. Juveniles roosted with their mothers prior to weaning, and then roosted in separate associations. Extraliminally, vocalizations (audible to humans) include comparatively deep, loud, short chirping or squeaking (Macdonald & Barrett 1993).

Reproduction and Population Structure Litter-size (Algeria): one (n = 9); other ♀♀ seen with only one young attached. At 35–36°N in NW Algeria, the reproductive chronology is restricted seasonal monoestry, with births in May and early Jun (based on histology of reproductive organs and year-round observations by Kowalski *et al.* 1986). Females reach sexual maturity when three years old; ♂♂ when two years old. In a spring sample of both ♂♂ and ♀♀, immature and adult animals were discriminated histologically. Sex ratio at birth close to 1 : 1.

Predators, Parasites and Diseases Ectoparasites in North Africa include a flea *Rhinolophopsylla unipeptinata* (Siphonaptera: Ischnopsyllidae); bat-flies *Nycteribia latreillei*, *N. schmidli*, *Penicillidia dufouri*, *P. conspicua*, *Phthiridium biarticulatum* (Diptera: Nycteribiidae) and *Brachytarsina africana*, *B. kollari* (Diptera: Streblidae); and a tick *Carios boueti* (Acari: Argasidae) (Anciaux de Faveaux 1984). For more information, see Beaucournu & Kowalski (1985).

Conservation IUCN Category: Vulnerable (assessed from extralimital as well as African data).

Major threat: ongoing human-induced destruction and degradation of habitat.

Rhinolophus ruwenzorii RWENZORI HORSESHOE BAT

Fr. Rhinolophe du Rwenzori; Ger. Ruwenzori-Hufeisennase

Rhinolophus ruwenzorii J. Eric Hill, 1942. Am. Mus. Novit., 1180: 1. South side of Butahu Valley, 2286 m, W slope of Rwenzori Mts, DR Congo.

Taxonomy Species-group: *maclaudi* (Fahr *et al.* 2002). Synonyms: none. Smith & Hood (1980) classified *R. ruwenzorii* (including *R. hilli* as a synonym) as a subspecies of *R. maclaudi*. Fahr *et al.* (2002) showed that both *R. ruwenzorii* and *R. hilli* are clearly differentiated from *R. maclaudi* and re-instated their status as distinct species. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); large for an African rhinolophid (FA: 55–62 mm); anterior upper premolar usually within toothrow; connecting process greatly reduced, very low and concave; lancet comparatively short and subtriangular; sella upright with concave sides, broadened tip and greatly enlarged basal lobes; horseshoe with lateral leaflets and median emargination; no axillary tufts. Sexes similar. Pelage soft, woolly; mid-dorsal hairs 13–14 mm. Dorsal pelage medium to dark brown or smoky-brown. Ventral pelage paler than dorsal pelage. Orange-phase: not yet reported. No axillary tufts on adult ♂♂. Ears comparatively medium-long (32–38 mm) and relatively long (60.3 [57–66]% of FA, $n = 19$), each with eight internal folds; antitragus very large. Noseleaf with lancet subtriangular, tip bluntly pointed, height of lancet only moderately exceeding height of sella. Connecting process greatly reduced, low and concave, leaving a deep emargination between sella and lancet. Sella naked, upright and more or less parallel to lancet (i.e. not inclined forward), sides concave, top distinctly broadened and rounded (spoon-shaped); narial lobes at base of sella greatly enlarged, forming an almost circular cup. Nostrils bordered by semi-circular, conspicuously raised rims that are parallel to the inner cup (therefore not reaching anterior margin of horseshoe). Horseshoe of medium breadth (10.8–12.6 mm); lateral leaflets present; median emargination conspicuous. Lower lip with a well-developed median groove and either two poorly-developed lateral grooves or no lateral grooves. Wings and interfemoral membranes dark grey. First phalanx of fourth finger relatively long (27.0 [26–28]% of fourth metacarpal, $n = 18$). Tibia 41.1 (38–46)% of FA, $n = 19$.

Skull large, slender; zygomatic arches broad but comparatively weak; zygomatic width < mastoid width. Rostrum robust; rostral emargination squarish; premaxillae broad. Nasal swellings high; chambers (viewed dorsally) roughly circular (posterior indentation weak). Frontal depression very deep. Braincase (viewed dorsally) constricted behind mastoid process; viewed laterally, the highest point is clearly behind the glenoid process (cf. *R. maclaudi*). Sagittal crest moderate anteriorly, poorly developed posteriorly. Infraorbital bridge moderately short and stout. Interpterygoid groove very deep. Palatal bridge relatively long (41–47% of C–M³; Csorba *et al.* 2003). Anterior upper premolar small, within toothrow or only slightly displaced labially; canine and posterior premolar separated. Middle lower premolar small, slightly to clearly displaced labially; distance between anterior and posterior lower premolars variable. Lower molars comparatively small (cf. other species in *R. maclaudi* group). Dental formula $^{1123}/_{2133} = 32$. For detailed comparison of

R. ruwenzorii with other species in *R. maclaudi* group, see Fahr *et al.* (2002).

Geographic Variation None.

Similar Species Three other *Rhinolophus* in Africa have a greatly reduced, low and concave connecting process (Table 14, p. 304):

Rhinolophus hilli. Height of lancet conspicuously exceeding height of sella. Smaller (FA: 54, 54 mm; CrnC: 23.0, – mm; GWS: 10.9, 11.2 mm; C–M³: 7.9, 8.1 mm). Skull with braincase not conspicuously constricted behind mastoid process; infraorbital bridge shorter and stouter; lower molars comparatively large. Nearly sympatric.

R. maclaudi. Larger (FA: 64–69 mm; CrnC: 29.0–30.1 mm). Ears longer (40–46 mm) with 10–12 internal folds. Sella inclined forward, lateral margins parallel-sided. Horseshoe broader (15–16 mm), no lateral leaflets, median emargination small or absent; nostrils bordered laterally by more or less straight and parallel rims. Skull with highest point at height of glenoid process; zygomatic width usually > mastoid width; infraorbital bridge slender and longer. West Africa.

R. ziamia. Ears with 11–12 internal folds. Skull larger (CrnC: 26.1–26.2 mm, C–M³: 8.9, 9.0 mm). Sella inclined forward. Horseshoe broader (11.5, 11.6 mm), no lateral leaflets, median emargination inconspicuous or absent; nostrils bordered laterally by more or less straight and parallel rims. Skull with zygomatic width ≥ mastoid width; infraorbital bridge much longer and more slender. West Africa.

Distribution Endemic to Africa. Apparently restricted to ca. 20,740 km² in the Afromontane–Afroalpine BZ flanking the Albertine Rift Valley. Known from 13 localities in the Rwenzori Mts (DR Congo and Uganda), Kivu and Kibali–Ituri Forests (DR Congo), Bwindi–Impenetrable Forest (Uganda) and Mutura (NW Rwanda) (Fahr *et al.* 2002). The distribution of the *Rhinolophus maclaudi* species-group is very disjunct and resembles that of the otter-shrews (genus *Micropotamogale*) (see profile of *R. maclaudi*).

Habitat Mostly recorded in (sub-) montane forests, but marginally also in lowland rainforests. Smith & Hood (1980) characterized the vegetation of the known localities as ‘Montane Evergreen/Bamboo forest’: they mist-netted one specimen in dense undergrowth near a dense bamboo forest. The known altitudinal range covers 1066–2667 m (median 1901 m, $n = 14$).

Abundance Uncertain; apparently very localized and rare. Only 36 specimens known.

Adaptations Most specimens have been captured in caves or artificial substitutes such as mines. Hayman (1960a) reported that the presence of *R. ruwenzorii* in a cave was indicated by rather loud squeaks

*Rhinolophus ruwenzorii*

as these bats took wing. Known to share day-roosts with *Rousettus lanosus*, *Rhinolophus clivosus* and *Hipposideros caffer* (Hill 1942, Smith & Hood 1980), the latter population probably representing *H. ruber*.

Foraging and Food Foraging behaviour not known. Stomachs and intestines of five adults contained remains of large moths (probably Noctuidae, Geometridae and Arctiidae), including their masticated wings and legs, which suggests that the prey is consumed whole with little culling of extremities (Smith & Hood 1980). The estimated body size of the insects was 8–12 mm with a wingspan of 25–35 mm (Smith & Hood 1980).

Echolocation No information. Call-shape probably FM/CF/FM (as in other *Rhinolophus*) and, based on the comparatively large size of this bat, the CF-frequency is likely to be rather low for a *Rhinolophus*.

Social and Reproductive Behaviour Roosts singly or in small groups of up to ten individuals (median = 3 individuals, $n = 7$) (Hayman 1960a, Smith & Hood 1980, unpublished museum data). One group consisted of three ♂♂ and four ♀♀, one of each sex being immature (Smith & Hood 1980). The majority of museum records are either single specimens or small series of one or two individuals.

Reproduction and Population Structure Litter-size: no information. Reproductive chronology not known. At ca. 1°S (Impenetrable Forest, Kigezi Highlands, SW Uganda), ten bats taken from mines in late Mar included four adult ♀♀ that had probably been lactating very recently, two large juveniles with unfused epiphyses, one ♂ with scrotal testes (4 mm in length) and three ♂♂ with abdominal testes (3 mm in length) (Smith & Hood 1980). These data indicate that at least some births occur in ca. early to mid-Feb and suggest reproductive synchrony, but there are no data for other months. The ♂ : ♀ sex ratio in museum collections is 1 : 0.6 ($n = 32$).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Vulnerable.

Major threats: loss and degradation of habitat (the region has one of the highest rural population densities in Africa and the protected areas are affected by recent civil wars); highly dependent on caves and mines and therefore vulnerable to disturbance at day-roosts and exploitation as bushmeat. Population trend not known but population size probably small. Most records are from 1926 to 1967 with a few additional records from 1982 to 1997. See also Distribution and Abundance.

Rhinolophus sakejiensis SAKEJI HORSESHOE BAT

Fr. Rhinolophe de Sakeji; Ger. Sakeji-Hufeisennase

Rhinolophus sakejiensis Cotterill, 2002. J. Zool., 256: 166. Kavunda (11° 17' S; 24° 21' E), Ikelenge pedicle, Mwinilunga District, NW Zambia.

Taxonomy Species-group: *ferrumequinum*. Synonyms: none. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid;

anterior upper premolar absent; connecting process rising to a high rounded peak; lancet long and hastate; sella with slightly concave sides; no axillary tufts; first phalanx of fourth finger relatively long; dorsal pelage bright brownish-orange in all three known specimens (cf. *R. deckenii*). Sexual dimorphism: no information, only three ♂♂ known.

Pelage of medium length, soft, fluffy. Dorsal pelage bright brownish-orange; hairs orange with darker tip. Ventral pelage bright yellowish-orange. Eyes surrounded by darker, brown pelage. Grey-phase not known. No axillary tufts on adult ♂♂. Ears dark brown, comparatively and relatively short (20–22 mm, 39 [37–40]% of FA). Noseleaf with lancet hastate. Connecting process rising steeply to a high, narrow, rounded peak, much higher than sella (Figure 59l). Sella naked, sides slightly concave, top broad, rounded and angled forward. Horseshoe of medium breadth (ca. 10–11 mm), not covering whole muzzle; lateral leaflets present; median emargination wide and deep. Lower lip with a prominent median groove (lateral grooves faint). Wings and interfemoral membrane dark blackish-brown. First phalanx of fourth finger relatively long, 27% of fourth metacarpal, $n = 1$. Tibia 47% of FA, $n = 1$. Baculum trumpet-shaped with dorsoventrally flattened shaft, length 4.2 (3.9–4.5) mm, $n = 3$ (Cotterill 2002a).

Skull very robust; zygomatic arches sturdy; zygomatic width greater than mastoid width. Nasal swellings relatively low; not smoothly rounded. Frontal depression extremely shallow; supraorbital ridges indistinct. Sagittal crest well developed anteriorly, weak posteriorly. Interpterygoid groove shallow. Palatal bridge ca. 33% of $C-M^3$ (Csorba *et al.* 2003). Anterior upper premolar absent in all three known specimens; canine and posterior premolar in contact. Middle lower premolar also absent in these specimens; anterior and posterior lower premolars in contact. Anterior lower premolar ca. half size of posterior lower premolar. Dental formula $^{1113}/_{2123} = 28$.

Geographic Variation No information.

Similar Species Four other *Rhinolophus* occurring south of the Equator have the following combination of characters: anterior upper premolar fully displaced labially or absent, connecting process rounded, sella naked (or with sparse short hairs only) (Table 14, p. 304):

Rhinolophus clivosus. Connecting process rounded but sometimes smoothly curved and sometimes slightly angular; slightly to clearly higher than sella. Horseshoe breadth 6.6–9.6 mm. Skull smaller (CrnC: 18.1–22.8 mm, $C-M^3$: 6.7–8.9 mm).

R. darlingi. Smaller (FA: 42–50 mm, CrnC: 18.5–20.8). Apparently no orange-phase. Horseshoe narrower (7.1–8.7 mm). Skull with nasal swellings moderately high; frontal depression shallow to moderately deep; supraorbital ridges prominent. Anterior upper premolar present or absent; canine and posterior premolar usually separated by small gap.

R. deckenii. Dorsal pelage greyish-brown: apparently no orange-phase. Connecting process rounded. Known only from East Africa.

R. silvestris. Anterior upper premolar present, displaced labially. Connecting process smoothly rounded and lower. Lancet subtriangular with slightly concave sides. Skull with nasal swellings of medium relative height; frontal depression moderately deep; supraorbital ridges prominent.

Distribution Endemic to Africa. Known only from the type locality (in Zambia), which lies between the Sakeji and Zambezi Rivers, ca. 11 km north-north-east of the source of the Zambezi R., at 1388 m. This locality is in the Zambezian Woodland BZ.

Rhinolophus sakejiensis

Habitat Wetter miombo woodland mosaic, with evergreen forest along the drainage lines and tall, deciduous, closed-canopy miombo woodland (dominated by *Brachystegia floribunda*) on the higher ground. There are flooded caves formed from granitic boulders along the perennial rivers and streams of the region (Cotterill 2002a, b).

Abundance Not known. Only three specimens known.

Remarks The three specimens, two adult ♂♂ and a young ♂, belonged to a group of six found roosting during the day; they were hanging in evergreen foliage on the underside of a branch at the base of a large tree. This is an unusual day-roost for a rhinolophid and perhaps is atypical for this species. At the type locality, *R. sakejiensis* is sympatric with *R. clivosus zuluensis*, a very similar species.

Conservation IUCN Category: Data Deficient.

Probably threatened by loss of habitat, especially of mesic miombo woodland and gallery forest, in its area of occupancy (Cotterill 2002a).

F. P. D. Cotterill

Rhinolophus silvestris FOREST HORSESHOE BAT

Fr. Rhinolophe sylvestre; Ger. Wald-Hufeisennase

Rhinolophus silvestris Aellen, 1959. Arch. Sci. Phys. Nat. Geneve 12: 228. N'Dumbu Cave, Latoursville, Gabon.

Taxonomy Taxonomy controversial. The first specimen was identified with *R. fumigatus* by Sanborn (1953). Aellen (1959) described *silvestris* as a species distinct from *fumigatus*, but suggested that it might prove to be a western forest subspecies of *R. deckenii*. Hayman & Hill (1971) treated both *deckenii* and *silvestris* as subspecies of *R. clivosus*. Koopman (1975) considered both *silvestris* and *deckenii* to be closely related but specifically distinct, and related to the *fumigatus*–*eloquens*–*hildebrandtii* complex. Aellen & Brosset (1968) considered *R. silvestris* and *R. deckenii* to have distinctly different characters, but suggested that there might be populations located between the geographic ranges of these species that could be intermediate in character. The phylogenetic analysis of Bogdanowicz & Owen (1992) indicated that *R. silvestris* is slightly more closely related to *R. alcyon* than to *R. deckenii*. In contrast, comparison of the bacula of *R. silvestris* and *R. deckenii* supports the hypothesis that these are sister species restricted to the W Congo Basin and the East African coast, respectively (Cotterill 2002a). Csorba *et al.* (2003) consider the differences between these two species to be very slight. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium-sized for an African rhinolophid; anterior upper premolar displaced labially; connecting process rounded; lancet subtriangular; sella with concave sides; baculum with rounded shaft (cf. *R. deckenii*). Difficult to distinguish from *R. deckenii* except by distribution and baculum morphology (see Similar Species). Sexes apparently similar. Pelage of medium length, soft, fluffy. Dorsal pelage rusty-brown. Ventral pelage paler. Orange-phase not yet known. Axillary tufts: no information. Ears comparatively medium–short (22, 23 mm) and relatively short (ca. 42% of mean FA). Noseleaf with lancet subtriangular, sides slightly concave, tip bluntly pointed. Connecting process smoothly rounded, higher than sella. Sella naked, sides concave, top broad and rounded. Horseshoe of medium breadth (9.5, 10 mm), covering muzzle; median emargination deep; no information about lateral leaflets. Lower lip with a well-defined median groove and two poorly defined lateral grooves. Wings and interfemoral membrane brown. First phalanx of fourth finger relatively long (ca. 31% of fourth metacarpal). Mean tibia 42.4% of mean FA. Baculum trumpet-shaped with rounded shaft, length 4.1 mm, $n = 1$ (Cotterill 2002a).

Skull robust; zygomatic arches sturdy; zygomatic width much greater than mastoid width. Nasal swellings of medium relative height; lateral profile smoothly rounded. Frontal depression moderately deep; supraorbital ridges prominent. Sagittal crest well developed. Palatal bridge of medium relative length (31–34% of C–M³; Csorba *et al.* 2003). Interpterygoid groove shallow but distinct. Anterior upper premolar minute, fully displaced labially; canine and posterior premolar in contact or almost so. Middle lower premolar minute

and fully displaced labially, or absent; anterior and posterior lower premolars in contact. Dental formula $^{1123}/_{2133} = 32$ or $^{1123}/_{2123} = 30$.

Geographic Variation None recorded.

Similar Species Four other African *Rhinolophus* occurring south of the Equator have the following combination of characters: anterior upper premolar fully displaced labially or absent; connecting process rounded; sella naked (or with sparse short hairs only) (Table 14, p. 304):

- Rhinolophus clivosus*. Lancet hastate. Horseshoe narrower (6.6–9.6 mm), narrower than muzzle. Connecting process higher. Skull with nasal swellings very low; frontal depression very shallow; supraorbital ridges weak. Interpterygoid groove absent or very indistinct. Upper canine and posterior premolar always in contact.
- R. darlingi*. Horseshoe narrower (7.1–8.7 mm). FA shorter (42–50 mm). Skull smaller (CrnC: 18.5–20.5, C–M³: 6.7–7.3 mm).
- R. deckenii*. Known only from East Africa. Morphometrically almost indistinguishable. Nasal swellings lower. Baculum with flattened, spatulate shaft.
- R. sakejensis*. Anterior upper premolar absent. Connecting process rising to high rounded peak. Lancet hastate. Skull with nasal swellings lower; frontal depression shallow; supraorbital ridges indistinct.

Distribution Endemic to Africa. Only known from the Rainforest BZ and from very nearby in the Southern Rainforest–Savanna Mosaic. Recorded only from Latoursville (Aellen 1959), Benga (Justine 1989) and Bélinga in Gabon, and from La Bamba and Meya-Nzouari in Congo (Csorba *et al.* 2003).

Habitat Dense rainforest in vicinity of caves.

Abundance Apparently rare; very few specimens known. See Conservation.

Remarks One of the most poorly known species of African bats. All specimens have been taken in caves, in which they roost by day. These caves include the Grotte de Maya-Nzouari in Congo, described in the profile of *R. adami*. From this limestone cave, one adult ♂ and five adult ♀♀ were collected on 26 July 1963, and three juveniles, two immature ♂♂ and one immature ♀ were collected on 25 November 1964, indicating that parturition occurs in this cave (Aellen & Brosset 1968): it is not known if other *R. silvestris* were present at the same time. This cave was also occupied by *Rousettus aegyptiacus*, *Rhinolophus adami*, *Hipposideros ruber*, *H. gigas*, *Triaenops afer* and *Miniopterus minor* (Adam & Le Pont 1974). Ectoparasites include bat-flies *Penicillidia fulvida* (Nycteribiidae) (Anciaux de Faveaux 1984).

Rhinolophus silvestris

Conservation IUCN Category: Data Deficient.

Only 12 specimens were collected (and none others reported) from only one of 45 caves investigated for the presence of bats over a period of ca. seven years (Adam & Le Pont 1974). Furthermore, it was not recorded from the nearby Mayombe and lower Kouilou regions of Congo, nor from the Haut-Ivindo region of Gabon, nor from Kikwit

(05° 13'S, 18° 49'E), DR Congo, during extensive investigations by other authors (for details, see profile of *R. adami*). As indicated by Dowsett *et al.* (1991), this species is potentially at risk because it roosts in caves occupied by fruit bats which may be hunted for food. Its status needs investigation.

Rhinolophus simulator BUSHVELD HORSESHOE BAT

Fr. Rhinolophe de brousse; Ger. Buschveld-Hufeisennase

Rhinolophus simulator K. Andersen, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 384. Upper Mazoe Valley, Mashonaland, Zimbabwe.

Taxonomy Species-group: *capensis*. Synonyms: *alticolus*, *bembanicus*. Subspecies: two of uncertain status. Aellen & Brosset (1968) treat *bembanicus* as a distinct species. However, the holotype of *bembanicus* no longer exists and until further specimens are available, its status remains uncertain (Ansell & Dowsett 1988). Possibly *alticolus* is also a distinct species (Csorba *et al.* 2003); for differences, see Geographic Variation. This form is considered distinct by Eisentraut (1963), Rosevear (1965), Hayman & Hill (1971) and others, but as conspecific with *R. simulator* by Koopman (1975), Hill & Morris (1971), Grubb *et al.* (1998) and Kock *et al.* (2000). Chromosome number (*R. s. simulator*, South Africa): 2n = 58; aFN = 60. X = large subtelocentric, Y = small submetacentric (Rautenbach 1986).

Description Small microbat with noseleaf (posterior component subtriangular with erect tip); medium–small for an African rhinolophid; anterior upper premolar within tooththrow; connecting process rounded; lancet triangular or hastate; sella with almost parallel or slightly concave sides, narrowest part of sella ca. 1.8 mm; no axillary tufts; E: 18–23 mm. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs 8–9 mm. Dorsal pelage variable, dark sepia brown, medium brown, greyish-fawn, brownish-grey or grey; sometimes yellowish; hairs with

paler base. Ventral pelage notably paler, sometimes whitish. Orange-phase not known except, according to Kingdon (1974), in East Africa (but this needs confirmation). No axillary tufts on adult ♂♂. Ears comparatively and relatively short (18–23 mm, 45 [40–50]% of FA). Noseleaf with lancet subtriangular with sides straight or slightly concave (*R. s. alticolus*) or hastate (*R. s. simulator*). Connecting process rounded, higher than sella (*R. s. alticolus*) or ca. same height (*R. s. simulator*). Sella naked, sides almost parallel or slightly concave; narrowest part 1.5–1.7 mm (0.1–0.2 mm broader before preservation) (cf. *R. swinnyi*). Narial lobes at base of sella comparatively well developed (cf. *R. swinnyi*, *R. denti*). Horseshoe narrow (6.7–9.0 mm); lateral leaflets present in *R. s. alticolus*, very indistinct in *R. s. simulator*; anterior margination a deep notch. Lower lip with three grooves (lateral grooves occasionally indistinct). Wings dark brown to dark greyish-brown, darker near body; interfemoral membrane almost black. First phalanx of fourth finger of medium relative length in both subspecies (23.2 [20–25]% of metacarpal, n = 29). Tibia 40.0 (36–44)% of FA, n = 23 (including both subspecies).

Skull delicate; zygomatic arches thin; zygomatic width ≤ mastoid width. Nasal swellings relatively high, rounded. Frontal depression moderately deep; supraorbital ridges prominent. Sagittal crest very low.

Palatal bridge usually 29–34% of $C-M^3$, but up to 38% in *R. s. alticolus* (Csorba *et al.* 2003). Anterior upper premolar small to medium-sized, within toothrow; canine and posterior premolar well separated. Lower canines smaller than upper canines (cf. *R. landeri*). Middle lower premolar minute and fully displaced labially or (occasionally) absent; anterior and posterior lower premolars in contact. Anterior lower premolar less than half height of posterior premolar. Dental formula usually $^{1123}/_{2133} = 32$ or occasionally $^{1123}/_{2123} = 30$.

Geographic Variation Two subspecies are tentatively recognized here, but possibly *alticolus* is a distinct species (see Taxonomy):

R. s. alticolus: Guinea, Liberia, Nigeria, Cameroon. Rainforest and savanna. Dorsal pelage dark sepia brown. Lancet triangular, horseshoe broader, sella larger (Kock *et al.* 2000). Measurements and cranial morphology similar.

R. s. simulator: eastern Africa from Ethiopia to KwaZulu–Natal, South Africa. Mainly woodland savannas. Dorsal pelage medium brown to grey. Lancet hastate, horseshoe narrower, sella smaller (Kock *et al.* 2000).

Similar Species Five other *Rhinolophus* in Africa have the anterior upper premolar within the toothrow and the connecting process rounded (Table 14, p. 304):

Rhinolophus maendeleo. Lancet subtriangular, horseshoe probably almost always broader (8.2, 8.4 mm). FA longer (48, 49 mm), cf. 42–47 mm for *R. simulator* in area of sympatry.

R. swinnyi. Ears on average shorter (17 [15–20] mm). Sella narrower (narrowest part 1.2–1.3 mm); lobes at base of sella low. Skull with frontal depression very shallow, sometimes almost flat; supraorbital ridges weak.

R. d. denti. Lancet subtriangular. Often smaller (FA: 40–44 mm; E: 19 [18–21] mm; CrnC: 16.4 [15.8–17.0] mm). Lobes at base of sella low. Skull with frontal depression shallow; supraorbital ridges weak. Rostrum shorter and narrower. Semi-arid savanna and desert. In southern Africa, not recorded east of 25° E.

R. capensis. Connecting process higher than sella. Body measurements larger on average (FA: 48.8 [47–51] mm). Skull larger (CrnC: 20.0–21.1 mm; $C-M^3$: 7.2–7.8 mm). Frontal depression shallow; supraorbital ridges weak. As yet, known only from the Cape Province of South Africa.

R. adami. Ears longer (25, 26 mm). Lancet subtriangular with slightly convex sides, horseshoe broader (8.5, 9.0 mm). Palatal bridge relatively long (42, 44% of $C-M^3$). Rainforest of DR Congo and not known to be sympatric.

Distribution Endemic to Africa. Distribution very disjunct. In West Africa, *R. s. alticolus* is known from the Guinea Savanna BZ (Jos Plateau), the Northern Rainforest–Savanna Mosaic, marginally in the Rainforest BZ, and in the Afromontane–Afroalpine BZ of the Cameroon Mountains. Recorded from Guinea, Liberia, Nigeria, Cameroon. In the east, *R. s. simulator* is mainly recorded from the Somalia–Masai Bushland, Coastal Forest Mosaic and Zambezi Woodland BZs, and the Afromontane–Afroalpine BZ of the Ethiopian Highlands, but it extends marginally into the Eastern Rainforest–Savanna Mosaic and Sudan Savanna BZ. Recorded from S

Rhinolophus simulator

Sudan and Ethiopia southwards to Northern Province and KwaZulu–Natal in South Africa. Mapped from country checklists (see order Chiroptera), other literature and museum records.

Habitat In West Africa, habitats include montane forest (Mt Nimba, Cameroon Highlands), rainforest at 130 m (inland Cameroon), and the forest–savanna mosaic of the Jos Plateau (Nigeria). In eastern Africa, mainly found in wetter woodland savannas dominated by *Brachystegia*, with some records in montane habitats and coastal mosaics. In KwaZulu–Natal (South Africa), associated with Valley Bushveld along lower reaches of major, east-flowing rivers (Taylor, P. 1998). Distribution probably dependent on presence of caves and/or abandoned mines (Cotterill 1998, Taylor, P. 1998). Rare in semi-arid savanna; absent from deserts.

Abundance *Rhinolophus s. alticolus* ‘occurs in large numbers’ in Cameroon (Rosevear 1965). *Rhinolophus s. simulator* is ‘rarely recorded’ in Malawi (Happold & Happold 1997), but is locally common in Zimbabwe (colonies of hundreds recorded).

Adaptations *Rhinolophus s. alticolus* roosts by day in caves; sometimes shares roosts with *R. alcyone* (Rosevear 1965) and other rhinolophids. At ca. 1400 m, *R. s. alticolus* was active in its roost during the day whereas *R. hillorum* and *R. guineensis* (as *R. fumigatus*) in the same roost were torpid (Brosset 1985).

Rhinolophus s. simulator: aspect ratio low; wing-loading very low; wing-tip rounded. Flight very variable in speed and highly manoeuvrable. Can take off from ground, predictably can hover briefly. Turns by banking (minimum radius <25 cm), and by stalling-and-twisting; individuals sustained flight within a 1×1×1 m enclosure for up to 107 circuits/flight (3 bats, 10 flights each; M. Happold unpubl.). Roosts by day in both wet and dry caves and mine-adits (Rautenbach 1982); not known to roost by day elsewhere. Hangs freely from ceilings. In Malawi, shares caves with *R. fumigatus*

and *Nycteris thebaica* (M. Happold unpubl.); in Zimbabwe, shares caves with *Hipposideros vittatus* (but each species roosts in separate chambers), *R. hildebrandtii* and *Miniopterus natalensis* (Cotterill 1998). In Zimbabwe, becomes torpid by day in cool-dry season but not in hot-wet season (Cotterill 1998). Predicted mean maximum urine concentration is comparatively low (2904 mOsmol/kg) (Happold & Happold 1988). Captive bats drank several times each night; they landed beside water and drank by lapping and sucking.

Foraging and Food Forages by slow-hawking; predictably also by gleaning. *Rhinolophus s. alticolus* enters lighted rooms at night (Rosevear 1965); *R. s. simulator* takes insects near lights (Smithers 1983). In Zambia, in wet season, the stomachs of 34 individuals contained moths (73% by volume), beetles (13%), termites (8%), crickets (5%) and some other insects (Whitaker & Black 1976). In dry season, the stomachs of 18 individuals contained moths (87%) and midges (13%).

Echolocation Call-shape FM/CF/FM. For *R. s. simulator* in Malawi, CF-frequency 84–86 kHz (1 ♀, 3 ♂♂ hand-held, 1 ♀ tethered); maximum variation by a hand-held individual 1 kHz; call-duration 24–34 ms (M. Happold unpubl.). In Zimbabwe, CF-frequency 78 kHz (one bat flying in laboratory) (Fenton & Bell 1981). In South Africa, CF-frequency (mean \pm 1 S.D.) is 82.7 ± 0.4 kHz; maximum call-duration 17.7 ± 3.9 ms (Taylor 1999a). In Swaziland, CF-frequency 81.3, 82.0 kHz (two bats; Monadjem 2005). The low CF-frequency recorded by Fenton & Bell (1981) suggests that the recorded individual was misidentified.

Social and Reproductive Behaviour *Rhinolophus s. alticolus* has been found roosting singly and in groups of four ♂♂, 25–30 not sexed, ca. 250 (mostly ♀♀), and ‘hundreds’ (Rosevear 1965, Brosset 1984). *Rhinolophus s. simulator* usually roosts in colonies of several dozens, but colonies of ca. 150 and ca. 300 individuals have been recorded in South Africa (Rautenbach 1982, Wingate 1983). Group-members often hang in clusters but without touching their neighbours (Smithers 1983), but ♀♀ with young attached huddle very closely together (Cotterill 1998). Doornhoek Tunnel (near Pietermaritzburg, South Africa) was occupied by ca. 150 individuals of both sexes; in spring, the ♀♀ migrated to maternity roosts elsewhere and then returned in late summer; the ♂♂ remained throughout the year (Wingate 1983 in Taylor, P. 1998). Maternity colonies are also reported by Rautenbach (1982) and Cotterill (1998).

Reproduction *Rhinolophus s. alticolus* is reported to be seasonally monoestrous by Brosset (1984), but no conclusive evidence is given. For *Rhinolophus s. simulator*, litter-size (Malawi, Zimbabwe, South

Africa) one (n = 26). At 18–19°S (Zimbabwe), the reproductive chronology is restricted seasonal monoestry, with spermatogenesis in ca. May; sperm-storage in epididymides for at least three months (during cool-dry season); copulation beginning in late Jun; implantation beginning in Jul; births in the wet season (mid-Nov) after gestation periods of 90–130 days (depending on absence or occurrence of a period of retarded embryonic development); lactation not exceeding seven weeks (Cotterill 1998). Juveniles become volant when less than three weeks old. In Malawi and Zambia, births have been reported in Nov, but no data for other months (Happold & Happold 1990a). In South Africa, scrotal size increased from Apr–Jul indicating copulation probably occurs in winter (Wingate 1983); pregnant ♀♀ observed in Sep; lactating ♀♀ in Jan (Rautenbach 1982).

Predators, Parasites and Diseases Ectoparasites include a flea *Echidnophaga aethiops* (Pulicidae), bat-flies *Brachytarsina africana*, *Raymondia waterstoni*, *R. hardyi* (Streblidae) and a tick *Ixodes simplex* (Ixodidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Nevertheless, the breeding and maternity colonies are especially vulnerable to disturbance in their day-roosts (Cotterill 1998).

Rhinolophus swinnyi SWINNY'S HORSESHOE BAT

Fr. *Rhinolophe de Swinnyi*; Ger. *Swinny's Hufeisennase*

Rhinolophus swinnyi Gough, 1908. Ann. Transvaal Mus. 1: 72. Ngqeleni District, Pondoland, South Africa.

Taxonomy Species-group: *capensis*. Synonyms: *piriensis*, *rhodesiae*. Subspecies: none. Considered closely related to *R. denti* and, based on close similarities in size, morphology and/or echolocation calls, it has often been suggested that *swinnyi* is a subspecies or synonym of *R.*

denti (e.g. Roberts 1914, Koopman 1966, Hayman & Hill 1971, Kock & Howell 1988, Bronner 1990). However, pending revision, *R. swinnyi* is tentatively retained here as a distinct species. Many references to *R. denti* in Zimbabwe actually refer to *R. swinnyi* (e.g. Fenton 1975, 1985,

Smithers & Wilson 1979, Fenton & Bell 1981, Taylor 1999a, Csorba *et al.* 2003). Chromosome number (South Africa): $2n = 58$; $aFN = 62$. $X =$ large subtelocentric, $Y =$ small metacentric (Rautenbach 1986).

Description Very small to small microbat with noseleaf (posterior component subtriangular with erect tip); small for an African rhinolophid; anterior upper premolar within tooththrow; connecting process rounded; lancet subtriangular with distinctly concave sides, or hastate; sella with slightly concave sides, narrowest part of sella 1.2–1.3 mm; no axillary tufts; ears 15–20 mm. Sexes similar. Pelage soft, fluffy; mid-dorsal hairs ca. 7 mm. Dorsal pelage pale grey to pale brown; hairs with pale cream at base. Ventral pelage paler, sometimes off-white or cream. In orange-phase, the dorsal pelage is bright orange. No axillary tufts on adult ♂♂. Ears comparatively and relatively short (15–20 mm, 35 [33–36]% of FA). Noseleaf with lancet subtriangular with markedly concave sides, sometimes almost hastate; tip bluntly pointed. Connecting process rounded, ca. same height as sella. Sella naked, sides slightly concave, narrowest point 1.2–1.3 mm, $n = 4$ (slightly narrower after preservation). Narial lobes at base of sella comparatively low (cf. *R. simulator*). Horseshoe narrow (6.0–7.4 mm), not covering whole muzzle; no lateral leaflets; median emargination a deep notch. Lower lip with three grooves but the lateral grooves are sometimes indistinct. Wings and interfemoral membrane brown. First phalanx of fourth finger of medium relative length (22.1 [21–25]% of fourth metacarpal, $n = 9$). Tibia 42.6 (39–47)% of FA, $n = 7$.

Skull delicate; zygomatic arches thin; zygomatic width = mastoid width. Nasal swellings rounded and of medium relative height. Frontal depression very shallow, sometimes almost flat; supraorbital ridges weak. Sagittal crest very low anteriorly, absent posteriorly. Palatal bridge of medium relative length, 30–34% of $C-M^3$ (Csorba *et al.* 2003). Anterior upper premolar small, within tooththrow; canine and posterior premolar well separated. Lower canines distinctly smaller than upper canines (cf. *R. landeri*). Middle lower premolar minute, fully displaced labially; anterior and posterior lower premolars in contact or almost so. Dental formula $^{1123}/_{2133} = 32$.

Geographic Variation No subspecies recognized. Csorba *et al.* (2003) report that the orange-phase appears to have become fixed in the topotypical population of *rhodesiae*.

Similar Species Five other African *Rhinolophus* have the anterior upper premolar within the tooththrow and the connecting process rounded (Table 14, p. 304):

- Rhinolophus simulator*. Ears on average longer (21 [18–23] mm). Sella broader (narrowest part 1.6–1.8 mm); lobes at base of sella higher. Skull with frontal depression moderately deep; supraorbital ridges prominent.
- R. denti*. Lancet subtriangular, sides slightly convex. Tibia often shorter (15–18 mm). Cranially indistinguishable except $CrnC$ usually shorter. Semi-arid savannas and deserts. In southern Africa, not recorded east of $25^\circ E$.
- R. capensis*. Connecting process higher than sella. Larger (FA: 47–51 mm). Skull larger ($CrnC$: 20.0–21.1 mm; $C-M^3$: 7.2–7.8 mm). Known only from the Cape Province of South Africa.
- R. adami*. Known only from rainforest in DR Congo.
- R. maendeleo*. Known only from coastal forests of Tanzania.

Distribution Endemic to Africa. Mainly recorded from the Zambezian Woodland BZ, with scattered records in the Afrotropical BZ (e.g. Uzungwa Mts in C Tanzania and Ntchisi F. R. in Malawi) and in the Coastal Forest Mosaic BZ (Zanzibar I. and South Africa), and a very isolated record in the Southern Rainforest–Savanna Mosaic at mouth of Congo R. There are scattered records in DR Congo, Tanzania, Zambia and Malawi, widespread records in Zimbabwe (Cotterill 1996a), and scattered records in E South Africa (Hayman *et al.* 1966, Anciaux de Faveaux 1978, Ansell 1978, Kock & Howell 1988, Bronner 1990, Happold & Happold 1997, Csorba *et al.* 2003).

Habitat In Tanzania, recorded from montane forest at 1350 m on the Uzungwa Mts (Kock & Howell 1988). In Malawi, known only from sub-montane seasonal rainforest at 1642 m on Ntchisi Mountain and adjacent open-canopy miombo woodland in Ntchisi F. R. (Happold & Happold 1997). In South Africa, recorded from montane forests (including *Podocarpus* mist forest) in KwaZulu–Natal and Cape Province (Bronner 1990). Recorded from savanna woodlands elsewhere in its geographic range (Cotterill 1996a).

Abundance Apparently rare south of Zambezi R.; widespread but scattered in Zimbabwe and only recorded singly or in small groups (Cotterill 1996a). Larger colonies recorded in SW Zambia (Ansell 1967), Katanga (DR Congo) and Zanzibar I. (Hayman & Hill 1971).

Adaptations Aspect ratio low; wing-loading very low; wing-tip rounded (M. Happold pers. comm.). Flight very variable in speed, and highly manoeuvrable. Can take off from ground; can almost hover. Turns by banking (minimum radius < 25 cm) and by stalling-and-twisting; individuals sustained flight within a $1 \times 1 \times 1$ m enclosure for up to seven circuits/flight (4 bats, 10 flights each). Roosts by day in totally dark positions in caves and old mines (Cotterill 1996a). Hangs from ceilings. In Zimbabwe, sometimes shares caves with much larger numbers of *R. simulator* (Cotterill 1996a).

Rhinolophus swinnyi

Food and Foraging Predicted to forage, by slow-hawking and possibly by gleaning, in cluttered places. In Zambia, in wet season, stomachs of 23 bats contained moths (55% by volume), beetles (26%), termites (6%) and also flies, midges, crickets, bugs and unidentified insects (Whitaker & Black 1976). In dry season, stomachs of nine bats contained moths (56%), midges (43%) and flies (1%).

Echolocation Call-shape FM/CF/FM. In Malawi, CF-frequency 102–104 kHz (3 ♀, 1 ♂ hand-held); maximum call-duration 37–74 ms (M. Happold pers. comm.). In Zimbabwe, CF-frequency 107 kHz, 110 kHz and 112 kHz (three bats; Fenton & Bell 1981, as *R. denti*): these bats have been confirmed as *R. swinnyi* (Monadjem *et al.* 2010). In Kruger N. P. (South Africa), CF-frequency 115 kHz (one bat flying in open) (Aldridge & Rautenbach 1987). The differences in CF-frequency at these different localities raise doubts about the identities of some of these bats (see Taxonomy).

Social and Reproductive Behaviour Single caves are occupied by 1–5 individuals, which roost singly or in twos scattered throughout the roost (Smithers 1983, Cotterill 1996a).

Reproduction Litter-size: one (n = 4). Reproductive chronology not known. At 13° 22' S (Ntchisi F. R., Malawi) 3 of 4 ♀ ♀ were heavily pregnant and one was lactating at beginning of wet season (early Nov); no data for other months (M. Happold pers. comm.). In C Zimbabwe, a ♀ had a full-term foetus on 14 Nov; no data for other months.

Predators, Parasites and Diseases Ectoparasites include bat-flies *Penicillidia pachymela*, *Phthiridium hoogstraali*, *P. ovale* (Diptera: Nycteribiidae), *Brachytarsina africana*, *Raymondia alulata*, *R. waterstoni* (Diptera: Streblidae) and mites *Eyndhovenia euryalis*, *Spinturnix walkerae*

(Acari: Spinturnicidae) and *Steatonyssus benoiti* (Acari: Macronyssidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Major threats: on-going, human-induced loss and degradation of habitat associated with agriculture and extraction of wood.

Rhinolophus zياما ZIAMA HORSESHOE BAT

Fr. Rhinolophe de Zياما; Ger. Zياما-Hufeisennase

Rhinolophus zياما Fahr, Vierhaus, Hutterer and Kock, 2002. Myotis 40: 109. Western edge of Sérédou near park station, border of Réserve de la Biosphère du Massif du Zياما, Guinée Forestière, Guinea.

Taxonomy Species-group: *maclaudi* (Fahr *et al.* 2002). Synonyms: none. Chromosome number: not known.

Description Medium-sized microbat with noseleaf (posterior component subtriangular with erect tip); one of the largest rhinolophids in Africa (FA: 60 mm); anterior upper premolar within tooththrow; connecting process greatly reduced, very low and concave; lancet elongated, narrow with distal half almost parallel-sided; sella parallel-sided, inclined forward, with greatly enlarged narial lobes; horseshoe without lateral leaflets and a median emargination; no axillary tufts. Sexual dimorphism: no information. Pelage long, soft, woolly. Dorsal pelage buffy-brown; hairs with pale buff base and pale brown tip. Ventral pelage paler than dorsal pelage, dirty buff with pale brown sheen. Orange phase: not yet reported. No axillary tufts on adult ♂ ♂. Ears comparatively and relatively long (35, 36 mm, 59, 61% of FA), each with 11, 12 internal folds; antitragus very large. Noseleaf with lancet long and narrow, distal half with sides almost parallel, tip rounded, height of lancet conspicuously exceeding height of sella. Connecting process

greatly reduced, low and concave, leaving a deep emargination between sella and lancet (Figure 59n). Sella inclined forward and therefore not parallel to lancet, sides almost parallel, top not distinctly broadened; lobes at base of sella greatly enlarged, forming a roughly heart-shaped corolla-like cup (Figure 60f). Nostrils bordered laterally by conspicuously raised, nearly straight and more or less parallel rims, which almost reach anterior margin of horseshoe. Horseshoe of medium breadth (ca. 11.5 mm), almost covering muzzle; no lateral leaflets; median emargination inconspicuous or absent. Lower lip with one groove. Wings and interfemoral membranes dark grey. First phalanx of fourth finger relatively long (26, 29% of fourth metacarpal). Tibia 44, 45% of FA.

Skull large, slender; zygomatic arches broad but comparatively weak, dorsally notched; zygomatic width ca. = mastoid width. Rostrum robust; rostral emargination U-shaped; premaxillae broad. Nasal swellings high-domed; chambers (viewed dorsally) roughly heart-shaped (with posterior indentation). Frontal depression very deep. Braincase (viewed dorsally) constricted behind mastoid process; viewed laterally, the highest point is clearly behind the glenoid process (cf. *R. maclaudi*).

Sagittal crest moderate anteriorly, poorly developed posteriorly. Infraorbital bridge very long and very slender. Interpterygoid groove very deep. Palatal bridge: no data. Anterior upper premolar small, within toothrow; canine and posterior premolar separated. Middle lower premolar small, slightly to clearly displaced labially; anterior and posterior lower premolars sometimes in contact, sometimes separated. Lower molars medium-sized (cf. *R. hilli*, *R. ruwenzorii*). Dental formula $^{1123}/_{2133} = 32$. For detailed comparison of *R. ziama* with other species in *R. maclaudi* group, see Fahr *et al.* (2002).

Geographic Variation No information but, based on small distribution, probably negligible.

Similar Species Three other African *Rhinolophus* have a greatly reduced, low and concave connecting process (Table 14, p. 304):

Rhinolophus maclaudi. Larger (FA: 64–69 mm; CrnC: 29.0–30.1 mm; C–M³: 10.5–10.8 mm). Ears longer (40–46 mm). Horseshoe broader (15, 16 mm). Skull with highest point at height of glenoid process; infraorbital bridge stouter. West Africa.

R. ruwenzorii. Each ear with eight internal folds. Skull smaller (CrnC: 23.7–25.6 mm; C–M³: 8.2–8.9 mm). Sella upright and more or less parallel to lancet. Horseshoe narrower (10.8–12.6 mm); lateral leaflets present, median emargination conspicuous; nostrils bordered by semi-circular rims. Skull with zygomatic width < mastoid width; infraorbital bridge much shorter and stouter. Mountains flanking Albertine Rift Valley.

R. hilli. Smaller (FA: 54 mm; CrnC: 23.0 mm; C–M³: 7.9, 8.1 mm). Each ear with nine internal folds. Sella upright and more or less parallel to lancet, sides slightly concave. Horseshoe slightly broader (12 mm), lateral leaflets present, median emargination conspicuous, rims around nostrils semi-circular. Skull with zygomatic width slightly < mastoid width; infraorbital bridge very short and stout. Mountains flanking Albertine Rift Valley.

Rhinolophus ziama

Distribution Endemic to Africa. Apparently restricted to a very small area in the Rainforest BZ (Western Region) and Afromontane–Afroalpine BZ of SE Guinea and NW Liberia. Only known from two localities in the highlands of SE Guinea and NW Liberia (the Massif du Ziama near Sérédou in Guinea, and the Wonegizi Mts in Liberia). These localities are ca. 32 km apart. The record from Liberia was published as *R. maclaudi* (Koopman 1994, Koopman *et al.* 1995, Csorba *et al.* 2003). The distribution of the *Rhinolophus maclaudi* species-group is very disjunct and resembles that of the otter-shrews (genus *Micropotamogale*) (see profile of *R. maclaudi*).

Habitat The holotype and two additional individuals were mist-netted in degraded forest near the protected area of the Massif du Ziama in Guinea at ca. 600 m; this locality has a mean annual precipitation of 2400 mm. Close to the type locality, the vegetation is composed of wetter evergreen lowland rainforest and semi-deciduous lowland rainforest, with montane forest at higher altitudes. The specimen from Liberia was caught in ‘undisturbed High Forest’ (Koopman *et al.* 1995), also at ca. 600 m.

Abundance Not known but seems extremely localized and rare. Only four individuals have been reported. The surrounding areas have been surveyed recently but the species has not been found elsewhere.

Remarks Day-roosts not known but it seems likely that *R. ziama* is dependent on caves as are other members of the *R. maclaudi* species-group. The echolocation call-shape is likely to be FM/CF/FM (as in other *Rhinolophus*) and, based on the comparatively large size of this bat, the CF-frequency is likely to be rather low for a *Rhinolophus*.

Conservation IUCN Category: Endangered.

Major threats: extent of occurrence extremely small and within an area seriously affected by the civil war in Liberia and the adjacent region of Guinea; remaining forests are increasingly affected by logging, mining and agriculture. Possibly threatened by disturbance and direct exploitation in its day-roosts.

Family HIPPOSIDERIDAE

OLD WORLD LEAF-NOSED BATS

Hipposideridae Lydekker, 1891. In: Flower & Lydekker, Mamm., Living and Extinct, p. 657.

| | | |
|----------------------------------|---------------------------|--------|
| <i>Asellia</i> (2 species) | Trident Leaf-nosed Bats | p. 360 |
| <i>Cloeotis</i> (1 species) | Short-eared Trident Bat | p. 364 |
| <i>Hipposideros</i> (14 species) | Old World Leaf-nosed Bats | p. 367 |
| <i>Triadenops</i> (1 species) | Trident Bat | p. 398 |

This is a polytypic family widely distributed in the tropical and sub-tropical regions of the Old World. Currently, the family contains nine extant genera (of which four are monotypic) and 81 extant species (Simmons 2005). In Africa, there are four genera and 18 currently recognized species, but some of these species probably contain cryptic species. The vast majority of species are in the genus *Hipposideros*. Hipposiderids have a complex noseleaf: the anterior component is usually very roughly horseshoe-shaped (as in Rhinolophidae) but there is no sella or connecting process, and the posterior component is either roughly elliptical, or 'trident-shaped' with three vertical projections (details below). Hipposiderids have roughly leaf-shaped ears with a minute tragus, toes with two phalanges, and a medium-length tail that is usually completely enclosed by the interfemoral membrane (but protrudes up to 3 mm in some African species of *Hipposideros* and up to 7 mm in *Asellia*). Hipposiderids resemble rhinolophids (which are closely related) but differ externally in the form of the noseleaf and the number of phalanges in the toes.

Hipposiderids (including African species) range in size from very small to very large. They have long soft dense pelage that is mostly brown, reddish-brown, grey or brownish-grey (in grey-phase), and most African species have an orange-phase. Most species have a small compact body and a rounded head with a short blunt muzzle, but some species are larger and more robustly built. The ears are mostly almost as broad as long and typically are well separated (but they are joined by a low band of skin in one species); the antitragus is conspicuous and the tragus is minute. The eyes are very small. The noseleaf is comprised of an anterior component that is roughly horseshoe-shaped in most species and often fringed with lateral leaflets, a central component that is little more than a thickened transverse pad, and an erect posterior component that is either low-arched or subtriangular in outline, or trident-shaped with three pointed projections. The central component has no sella or connecting process (cf. Rhinolophidae). Behind the posterior component, there is sometimes a frontal sac that opens through either a vertical or a horizontal slit. Many species of African hipposiderids are distinguished by the form of the noseleaf (see genus profiles). The wings are relatively large with short, rounded tips; the second finger has a long metacarpal but no bony phalanges. The hindlimbs are moderately long with small soles; the toes (excluding hallux) have two phalanges (cf. three in Rhinolophidae and other families). The tail is relatively short to medium (30–44% of TL); usually it is completely enclosed by the interfemoral membrane but it projects up to 7 mm beyond the membrane in *Asellia*, and up to 3 mm in some *Hipposideros*. Calcars are present. Females have one pair of pectoral nipples and one pair of pubic nipples. The skull is similar to that of the Rhinolophidae: for details of African species, see Hill (1963, 1982b). Because the nasal branches of the premaxillae are absent, and the palatal branches often lost during preparation of skulls, the greatest length of

Figure 63. Characters of African bats in the family Hipposideridae. (a) Flight membranes and bones of wing, hindlimb and tail (e.g. *Hipposideros ruber*). (b) Dorsal view of a skull in which the zygomatic width is much greater than the mastoid width (e.g. *H. abae*; RMCA RG 36693). (c) Dorsal view of a skull in which the zygomatic width is much less than the mastoid width (e.g. *H. jonesi*; RMCA).

skull (GLS) of hipposiderids is replaced by CrnC – the distance from the anterior of the upper canine to the most posterior part of the skull. The greatest width of the skull (GWS) can be either the zygomatic width (ZW) or the mastoid width (MW) or it can be variable (Figure 63). The sagittal crest varies from low to greatly developed and usually extends over both frontal and parietal bones of the braincase (cf. many Rhinolophidae). Nasal swellings are present; the degree of inflation

Figure 64. Sonograms of sequences of CF/FM echolocation calls emitted by four bats representing three species of Hipposideridae from Malawi (all hand-held) (M. Happold unpubl.). (a) Four calls by ♀ *Hipposideros ruber*, (b) four calls by ♂ *H. vittatus*, (c) three calls by ♀ *Triaenops afer* and (d) four calls by ♂ *T. persicus*. Time axis marked at intervals of 50 ms.

varies. Supraorbital ridges are usually low but definable, sometimes absent and sometimes prominent. In some species, the cochlea are expanded so the width of each one is equal to or greater than their distance apart. The dental formula is $^{1123}/_{2123} = 30$ except in *Asellia* and *Hipposideros megalotis*, which have only one upper premolar on each side. The upper incisor is usually weakly bicuspid, but the outer lobe may be greatly reduced or absent. The upper canine is longer than the other teeth and sometimes has anterior or posterior cusps. In *Hipposideros*, the length of the upper canine ranges from 38 to 54% of $C-M^3$, so 38–43% is relatively short, 44–49% is medium, and 50–54% is relatively long. The anterior upper premolar (P^2) is very small; it is often displaced labially so that the canine and posterior premolar (P^4) are in contact or nearly so, or it can be within the tooththrow or only slightly displaced, in which case the canine and posterior premolar are separated. The posterior upper premolar is long, sharp and somewhat similar to the canine in shape. The anterior lower premolar is typically lower than the posterior lower premolar, and has a smaller crown area.

Hipposiderids have very low to medium aspect ratios and very low to high wing-loadings. Their flight is variable: some fly slowly with considerable manoeuvrability; others fly more swiftly with greater agility but less manoeuvrability (Norberg & Rayner 1987). They can take off from the ground and some can hover briefly. Hipposiderids are insectivorous: the taxa and size of prey varies according to the size of the bat and the robustness of its teeth. Hipposiderids are often fly-catchers and gleaners but they also forage by slow-hawking, some to a greater extent than others. Unlike most rhinolophids, many hipposiderids forage in small groups. The echolocation calls are typically CF/FM in shape, with a sustained CF component and maximum energy in the second harmonic (Figure 64). Some (perhaps all) African hipposiderids can be recognized by the CF-frequency. The bimodal distribution of CF-frequencies recorded in a cave occupied by '*Hipposideros commersoni*' drew attention to the presence of two distinct species in this cave; they are now known as *H. gigas* and *H. vittatus*. Perhaps in some species, ♂♂ and ♀♀ use different frequencies (e.g. *Hipposideros caffer*, *Triaenops afer*) but this needs confirmation. The echolocation calls of hipposiderids are adapted to detect flutter (by exploiting Doppler-shifted echoes reflected from the fluttering wings of insects), and are particularly suitable for

densely cluttered environments (Neuweiler 1989). Hipposiderids, like rhinolophids, have nasal swellings (= rostral inflations, rostral swellings), which possibly facilitate the production of harmonics. Hipposiderids emit their echolocation calls through the nostrils, and the noseleaves direct a beam of sound in front of the bat and perhaps also modify the emitted sounds in other ways. While echolocating, the ears move independently with a rapid flickering movement, and the head moves up and down and from side to side to beam the sound in different directions. The rapid movements of the ears are correlated with the production of the echolocation calls, and the possible functions of the movements are discussed by Pye & Roberts (1970).

Hipposiderids are unable to scuttle over the ground, and apparently cannot climb. During the day, they roost in dark caves or cave-like day-roosts such as mines, tunnels, rock-crevices, hollow trees and dark places in buildings. They hang freely from footholds on horizontal ceilings or hang in contact from footholds on vertical surfaces. Some roost apart; some roost in contact with conspecifics. When roosting, the tail and interfemoral membrane folds up over the back and the wings fold around the chest so the body is almost enclosed by the flight-membranes. Some species hibernate, but hibernation is not known to occur in Africa although torpor for short periods during particularly cold weather has been reported for *Hipposideros caffer* in South Africa. Most African hipposiderids roost in large to very large colonies. The social organizations and mating systems of most species are not known, but a remarkable study of *H. beatus* by Brosset (1982) revealed that this species lives in monogamous family groups, and there is some evidence that the mating systems of *H. caffer* and *H. vittatus* are resource-based polygyny of some sort (see species profiles). Maternity colonies are established by some species. All African hipposiderids for which data are available are monotocous and seasonally monoestrous ($n = 6$ species). Species that occur both north and south of the Equator exemplify both boreal and austral chronologies. Reproductive delays have been documented for two species: delayed implantation in *Hipposideros caffer* at 10° N, and retarded embryonic development in *H. caffer* at 29° S, and in *H. ruber* at 7° S. Females carrying a juvenile have been mist-netted at night on two occasions, and I. L. Rautenbach observed that most of ca. 300 ♀♀ at a night-roost had young attached, indicating that the young

may be carried between day- and night-roosts and also on foraging flights (Ansell 1986a). Presumably the young cling to the pubic nipples as well as to the pectoral nipples while being carried.

The geological range of the family Hipposideridae is middle Eocene to Recent in Europe (but there are no hipposiderids in Europe at the present time), early Oligocene to Recent in Arabia, early Miocene to Recent in Africa, Pleistocene to Recent in Asia, late Oligocene to Recent in Australia (Hand & Kirsch 1998). Because they are predominantly cave-dwelling bats, their remains are frequently preserved in Cenozoic limestone sediments. The earliest known *Hipposideros* is from the early Miocene, and the subgenus *Syndesmotis* (into which *H. megalotis* is sometimes placed) appears to have separated from *Hipposideros* in the middle Miocene. Based on phylogenetic analyses, Bogdanowicz & Owen (1998) suggest that the Hipposideridae probably originated somewhere in the Oriental region. In contrast, based on evidence from fossils, Hand & Kirsch (1998) suggest that the family originated in Australia.

Hipposiderids have radiated into forests, savannas (especially woodland savannas) and arid habitats: the most extensive adaptive radiation has been within the genus *Hipposideros*. The majority of extant hipposiderids are found in the eastern half of the Old World tropics and sub-tropics: there are no temperate species (cf. Rhinolophidae). Of the 18 species in Africa, all species occur in the tropics but three species extend marginally either north (*Asellia tridens*) or south (*Cloeotis percivali*, *Hipposideros caffer*) of the tropics. Six species are found mainly or only in forests, six in both forest and savanna habitats, two mainly or only in savannas, two in both savanna and arid habitats, one only in arid habitats, and one (*H. caffer*) is found in all of these habitats. Nine species (50%) have been found in montane habitats, but none has been found only in montane habitats. Three or more species have been recorded at several localities, including:

Kagoro, Nigeria (Guinea savanna): *H. abae*, *H. jonesi*, *H. ruber* (Happold 1987).

Shimoni, Kenya (Coastal Forest mosaic with coral caves): *H. gigas*, *H. vittatus*, *T. afer* (Aggundey & Schlitter 1984).

Awash N. P., Ethiopia (grassland, thorn scrub with lava caves): *A. patrizii*, *A. tridens*, *H. vittatus*, *T. afer* (Largen *et al.* 1974).

Garamba N. P., DR Congo (Rainforest–Savanna mosaic with caves): *H. abae*, *H. beatus*, *H. caffer*, *H. cyclops*, *H. ruber* (Verschuren 1957).

Based on morphological data, the family Hipposideridae was placed in the superfamily Rhinolophoidea with the families Nycteridae, Megadermatidae and the very closely related Rhinolophidae (Simmons 1998, Simmons & Geisler 1998), but more recent molecular studies have contradicted many groupings based on morphological data (Simmons 2005). Some authors, including Koopman (1984, 1993, 1994) and Simmons (1998), follow Tate (1941) in considering the Hipposideridae to be a subfamily of the Rhinolophidae. However, the familial status of the Hipposideridae has been retained in the majority of books about African mammals and is tentatively retained here for several reasons. In addition to differences in the form of the noseleaves, the number of phalanges in the toes and the number of lower premolars, there are differences in the shoulder and pelvic regions. In the family Hipposideridae, the first and second ribs and corresponding vertebrae are fully fused, the lumbar vertebrae are frequently fused, and the pelvic girdle has a preacetabular foramen. In contrast, in the family Rhinolophidae, the first and second

ribs are only partially fused, there is no fusion of the lumbar vertebrae and no preacetabular foramen. Furthermore, the earliest fossil Hipposideridae (from the late Eocene and early Oligocene of France) were already distinct from the Rhinolophidae that occurred in the same deposits (Lekagul & McNeely 1977). However, the similarities between these taxa are greater than those between other families and they are evidently closely related. The family Hipposideridae has been reviewed by Hill (1963, 1982b) but not all of Hill's conclusions are supported by more recent phylogenetic studies. For example, it has been suggested that the genus *Hipposideros* is not monophyletic (see Genus *Hipposideros*). Furthermore, it has been indicated that the Hipposideridae is not monophyletic (Benda & Vallo 2009).

In Africa there are four genera:

Hipposideros. Posterior component of noseleaf roughly elliptical in outline (although the outline of upper margin varies from almost flat to low-arched or even subtriangular), without three projections (Figure 65a). Fourteen species currently recognized in Africa.

Asellia. Posterior component of noseleaf with three short, triangular projections (Figure 65b), tail protruding up to 7 mm beyond interfemoral membrane, only one upper premolar on each side, M³ greatly reduced (two ridges). Two species.

Cloeotis. Posterior component of noseleaf with three tall tapering projections (Figure 65c), tail completely enclosed by interfemoral membrane, FA: 31–39 mm, two upper premolars on each side, M³ not reduced (four ridges). One species.

Triaenops. Posterior component of noseleaf with three tall tapering projections (Figure 65d), tail completely enclosed by interfemoral membrane, FA: 49–61 mm, two upper premolars on each side, M³ not greatly reduced (three ridges). One species in Africa.

Meredith Happold

Figure 65. Noseleaves of representatives of the four genera of bats in the family Hipposideridae that are found in Africa. (a) *Hipposideros abae* (based on Rosevear 1965), (b) *Asellia tridens* (RMCA RG 31163), (c) *Cloeotis percivali* (based on Hill 1982b) and (d) *Triaenops afer* (based on Hill 1982b).

GENUS *Asellia*

Trident Leaf-nosed Bats

Asellia Gray, 1838. Mag. Zool. Bot. 2: 493. Type species: *Rhinolophus tridens* E. Geoffroy, 1813.

Figure 66. *Asellia tridens*. Skull (BMNH 1.5.5.17).

Asellia is a polytypic genus with only two species; neither is endemic to Africa. Distinguished from other African genera of hipposiderids by the following combination of characters: posterior component of

noseleaf with three subtriangular projections rising from the upper margin (i.e. somewhat trident-shaped – the central projection is pointed, the other two are blunt) (Figure 65b); tail projecting up to 7 mm beyond the interfemoral membrane. Furthermore, the posterior component of the noseleaf is not divided into deep cells by well-defined septa (cf. *Cloeotis* and *Triaenops*). Skull with sagittal crest greatly developed in the interorbital region; the deep rostrum and low braincase are of nearly equal height (Figure 66). Nasal swellings relatively small. Dental formula $^{1113}/_{2123} = 28$. The dentition is more modified than that of *Hipposideros*; the anterior upper premolar (P^2) is absent, the upper canine has a well-developed secondary cusp, and M^3 is considerably reduced, with only four cusps and two ridges. The species range in size from very small to small.

One species is widespread across most of Africa north of 12°N (extending further southwards in Ethiopia and Somalia) and extends extraliminally across Arabia to Pakistan. The other is confined to a small area in Ethiopia, Eritrea and offshore islands, extending extraliminally only as far as the nearby Saudi Arabian islands in the Red Sea. Both species are among the most desert-adapted bats; they are particularly tolerant of low relative humidities in their day-roosts (down to <30%).

Based on fossil evidence, Legendre (1982) noted that species of the extinct subgenus *Hipposideros* (*Pseudorhinolophus*) are morphologically similar to some recent taxa and could be ancestral to *Asellia*; this hypothesis is supported by the cladograms of Bogdanowicz & Owen (1998). The modern *Asellia* are reported from the Miocene of Europe (Astaratian) with *A. mariaetheresae* and Africa (Ternanian) with *A. vetus*. The karyotype of *Asellia tridens* is the nearest to the ancestral karyotype of the family.

The two species are:

A. patrizii. Smaller, FA: 38–43 mm, CrnC: 14.4–15.8 mm.

A. tridens. Larger, FA: 45–55 mm, CrnC: 16.5–19.3 mm.

Stéphane Aulagnier

Asellia patrizii PATRIZI'S TRIDENT LEAF-NOSED BAT

Fr. Trident de Patrizi; Ger. Patrizis Dreizackblattnase

Asellia patrizii De Beaux, 1931. Ann. Mus. Civ. Stor. Nat. Genova 55: 186. Gaarre [= Gahare], Dancalia, Ethiopia.

Taxonomy Synonyms: none. Chromosome number: not known.

Description Very small microbat with noseleaf (posterior component with three short projections); dorsally pale brownish-grey; tail projecting 3–5 mm beyond interfemoral membrane; FA: 38–43 mm. Sexual dimorphism: no information. Pelage soft, fluffy, dense; mid-dorsal hairs 6–7 mm. Dorsal pelage pale brownish-grey; hairs off-white or pale beige with brownish-grey at tip. Ventral pelage off-white. Ears well separated, naked, broad, height exceeding breadth; inner margin convex, outer margin convex with slight concavity below tip; tip shallowly pointed. Posterior component of

noseleaf with three short projections (the central one pointed, the outer two blunt), and with six cells arranged in a semi-circle below the projections – the outermost cells are open basally. Anterior component broad; two lateral leaflets on each side; no anterior median emargination; no hour-glass-shaped process. Wings and interfemoral membrane dark brown or sometimes paler; wing-membrane attaching to ankle. Third metacarpal long – slightly longer than fourth, much longer than fifth. Length of third metacarpal plus first phalanx is ca. 2–3 mm shorter than FA (cf. *A. tridens*). Interfemoral membrane small, rectangular, naked. Tail protruding 3–5 mm beyond interfemoral membrane.

Skull short, broad; zygomatic arches laterally flared with low jugal projection; zygomatic width > mastoid width. Nasal swellings well developed. Sagittal crest well developed and forming an evenly convex curve from the nasal swellings to the lambda. Upper incisor small, unicuspid. Upper canine powerful with well-developed secondary cusp at ca. half to two-thirds of its height. Anterior upper premolar absent; canine and large posterior premolar in contact. M³ greatly reduced and with only two ridges.

Geographical Variation No subspecies recognized.

Similar Species Three other hipposiderids in Africa have three vertical projections arising from the posterior component of the noseleaf:

Asellia tridens. Larger (FA: 45–55 mm; CrnC: 16.5–19.3 mm). Length of third metacarpal plus first phalanx is ca. 2 mm longer than FA.

Triaenops afer. Larger (FA: 49–60 mm; CrnC: 17.6–21.2). Tail fully enclosed by interfemoral membrane. Projections arising from posterior component of noseleaf are conspicuous, tall and tapering. Anterior component of noseleaf is broad with a conspicuous process (hour-glass shaped in outline) arising from the sides of a deep median emargination. Two upper premolars on each side; M³ not greatly reduced (three ridges).

Cloeotis percivali. Tail fully enclosed within interfemoral membrane. Ears shorter (7–11 mm). Projections arising from posterior component of noseleaf are tall and tapering. Two upper premolars

on each side; M³ not reduced (four ridges). Not known to be sympatric.

Distribution In Africa, known only from the Somalia–Masai Bushland and Afromontane–Afroalpine BZs in Ethiopia and Eritrea, including some small islands (Entedebir I., Nocra I.) in the Red Sea off the coast of Eritrea (Largen *et al.* 1974). Extraliminally: Saudi Arabian islands in the southern part of the Red Sea (Moeschler *et al.* 1990).

Habitat Recorded from very dry, open, rocky terrain, such as the semi-desert grassland, thorn scrub and volcanic rubble of the Awash N. P. in C Ethiopia (Hill & Morris 1971) and a lava field with scarce *Acacia* and other shrubs at Metahara, Shoa, Ethiopia (BMNH). Sea level (islands) to 1000 m in the Awash N. P.

Abundance Uncertain. Only small colonies have been observed, and few specimens have been collected. Populations are probably small and scarce.

Remarks Roosts by day in caves (including lava blister caves) and buildings, sometimes together with *A. tridens*. De Beaux (1931) observed *A. patrizii* leaving the roost and flying close to the ground while catching small insects. In Awash N. P., both sexes were observed in the same colony in Sep and Dec (Hill & Morris 1971).

Conservation IUCN Category: Least Concern.

Major threat: disturbance of roosts.

Stéphane Aulagnier

Asellia patrizii

Asellia tridens GEOFFROY'S TRIDENT LEAF-NOSED BAT

Fr. Trident du désert; Ger. Geoffroys Dreizackblattnase

Asellia tridens (E. Geoffroy, 1813). Ann. Mus. Natn. Hist. Nat. Paris 20: 265. Tombs of the Kings (Luxor) and Dadara (restricted to Luxor [= Thebes] by Kock 1969a), Egypt.

Taxonomy Originally *Rhinolophus tridens*. Synonyms: *diluta*, *italosomalica*, *murraiana*, *pallida*. Subspecies: four, three in Africa. Chromosome number (Tunisia): $2n = 50$; $aFN = 62$ (Baker *et al.* 1974).

Description Small microbat with noseleaf (posterior component with three short projections); dorsally pale brownish-grey with orange-phase; tail projecting up to 7 mm beyond interfemoral membrane; FA: 45–53 mm. Sexes alike in colour; based on forearm length, ♂♂ on average larger than ♀♀ in S Egypt but smaller than ♀♀ in Tunisia. Pelage soft, fluffy, dense; mid-dorsal hairs 5–9 mm. Dorsal pelage (grey-phase) pale brownish-grey; hairs off-white or pale beige with brownish-grey at tip. Ventral pelage (grey-phase) off-white. Orange-phase: dorsal and ventral pelage reddish to bright orange. Both colour phases and all intermediate colours have been observed in a single colony. Ears well separated, nearly naked, broad, height exceeding breadth; inner margin convex, outer margin convex with slight concavity below tip; tip shallowly pointed. Noseleaf as in Figure 65b. Posterior component with three short projections (the central one pointed, the outer two blunt), and with six cells arranged in a semi-circle below the projections – the outermost cells are open basally. Anterior component broad; two lateral leaflets on each side; no anterior median emargination; no hour-glass shaped process. Wings and interfemoral membrane with varying amounts of dark brown pigmentation – pale and translucent in some individuals. Wing-membrane attaching to ankle. Third metacarpal longer than fourth, much longer than fifth. Third metacarpal plus first phalanx ca. 2 mm longer than FA (cf. *A. patrizii*). Interfemoral membrane small, rectangular. Tail protruding up to 7 mm beyond interfemoral membrane.

Skull (Figure 66) short, broad; zygomatic arches laterally flared with low jugal projection; zygomatic width > mastoid width. Nasal swellings well developed. Sagittal crest well developed and forming an evenly convex curve from the nasal swellings to the lambda. Upper incisor small, unicuspid. Upper canine powerful with well-developed secondary cusp at ca. half to two-thirds of its height. Anterior upper premolar absent; canine and large posterior premolar in contact. M^3 greatly reduced and with only two ridges.

Geographic Variation Based on morphometric and colour variation, three main groups can be identified in Africa:

Large, dark animals: Morocco, Mauritania and N Egypt.

Small, pale animals: most of geographic range (Owen & Qumsiyeh 1987).

Smaller animals: Somalia and S Ethiopia (Koopman 1975).

The taxonomic status of these groups, whose differences could be local adaptations, needs confirming by genetic evidence.

Similar Species Three other hipposiderids in Africa have three vertical projections arising from the posterior component of the noseleaf:

Asellia patrizii. Smaller (FA: 38–43 mm; CrnC: 14.4–15.8 mm).

Length of third metacarpal plus first phalanx is ca. 2–3 mm shorter than FA.

Triaenops afer. Tail fully enclosed by interfemoral membrane. Projections arising from posterior component of noseleaf are conspicuous, tall and tapering; central projection taller than outer ones. Anterior component of noseleaf broad with a conspicuous process (hour-glass-shaped in outline) arising from the sides of a deep median emargination. Two upper premolars on each side; M^3 not greatly reduced (three ridges).

Cloeotis percivali. Tail fully enclosed within interfemoral membrane. Smaller (FA: 31–39 mm; CrnC: 12.0–13.5 mm). Projections arising from posterior component of noseleaf are tall and tapering. Two upper premolars on each side; M^3 not reduced (four ridges). Not known to be sympatric.

Distribution In Africa, this desert species has been recorded from the Sahara Arid and Sahel Savanna BZs (and marginally in the Sudan Savanna BZ) and from the most arid parts of the Mediterranean Coastal and Somalia–Masai Bushland BZs. Recorded from very scattered localities in Morocco (south of Atlas Mts), Algeria, Tunisia, Libya and Egypt (but not in coastal belt), and southwards to Mauritania, Gambia, Senegal, Mali, Burkina, Niger,

Asellia tridens

N Chad, N Sudan, Ethiopia and N Somalia (Kock 1969a, Koch-Weser 1984, Qumsiyeh 1985, Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991, Jones *et al.* 1993, Benda *et al.* 2004d). Extraliminally: through Arabia to Pakistan. A record from Zanzibar (Peters 1871) has never been confirmed (though often cited) and may be a mislabelled MNHN specimen (D. Kock pers. comm.).

Habitat Found in a wide variety of desert and semi-desert vegetation zones, mainly in oases or nearby. The extremely arid parts of the Sahara are avoided, and the distribution elsewhere is limited to areas with suitable day-roosts and supplies of insects.

Abundance Very common. The most commonly mist-netted bat in the Saharan Atlas and the Occidental Erg; also the most common bat in owl pellets in S Morocco and Algerian Sahara. Colonies number from ca. ten to several hundred individuals in Africa; up to 5000 extraliminally in Iran.

Adaptations Aspect ratio medium–low; wing-loading low (Jones *et al.* 1993). Flight predicted to be slow with great manoeuvrability; bats observed to make rapid twists and turns. By day, roosts in caves and mines (near the entrance), open wells and underground irrigation tunnels, old tombs, dark ruins and buildings. Clings in contact with walls. Surprisingly tolerant of light; roosts in lighted shelters and individuals were recorded flying in the daylight under palm trees in Morocco (Aulagnier & Thévenot 1986), and emerging from their day-roosts before dusk in Algeria (Kowalski & Rzebik-Kowalska 1991). Also very tolerant of low relative humidities in their day-roosts (down to <35%; Gaisler *et al.* 1972). Active all year round (Koch-Weser 1984). In Iraq, colonies are suspected to migrate in some parts of the geographic range; from winter to summer quarters in Apr–May, and back again from mid-Sep to mid-Nov (Al-Robaee 1966). Fat deposits have been observed during the wet season in Burkina (Koch-Weser 1984).

Foraging and Food Forages by slow-hawking and presumably by ground-gleaning; has been observed foraging around palm trees and buildings, and over water. Foraging flights are low with rapid twists and turns. Feeds mainly on large insects: Coleoptera, Hymenoptera, Orthoptera, Diptera and Lepidoptera (Jones *et al.* 1993, Whitaker *et al.* 1994, Feldman *et al.* 2000), and even on scorpions. There are important variations in diet, both locally and seasonally.

Echolocation Search-phase call-shape CF/FM. The CF-component is sometimes of very low amplitude, but is always present (Pye 1972): this is discussed in detail by Roberts (1972). For 11 Egyptian bats, the CF-frequency varied from 115 to 120 kHz; each individual emitted a narrow range of frequencies, and different individuals emitted different ranges of frequencies (Roberts 1972). For 18 Tunisian bats, resting, the CF-frequency was 111–124 kHz (the CF-frequency varied from bat to bat; individuals kept the frequency constant); bandwidth of terminal FM sweep 19–21 kHz; call-duration 7–10 ms; minimum intercall interval 27–215 ms (depending on degree of alertness) (Gustafson & Schnitzler 1979). Flying bats lowered their emission frequency to compensate for Doppler shifts caused by the flight movement; call-duration 9–11 ms; minimum inter-call interval 26 ms. For bats in a roost in

Gambia containing thousands of individuals, the CF-frequency was 108–122 kHz (frequency found to be negatively correlated with FA length within sexes); lowest frequency of the terminal FM sweep 97 kHz: call-duration 7.5–9 ms, inter-call interval 10–20 ms (Jones *et al.* 1993).

Social and Reproductive Behaviour Normally roosts in groups (colonies) containing, in Africa, ca. 10 to several hundred individuals (up to 500 in Egypt; Gaisler *et al.* 1972). In Morocco, sexes segregate in Mar when these bats move from their winter to their summer quarters. Pregnant ♀♀ establish maternity colonies; non-reproductive ♀♀ often roost with the ♂♂ (Brosset 1955, Brosset & Caubère 1960). Groups of subadults have been found in Egypt (Gaisler *et al.* 1972). In Burkina, ♂♂ and ♀♀ share the same roost throughout the year (Koch-Weser 1984), however sexual segregation perhaps occurs inside the roost, as in Iraq (Al-Robaee 1966).

Reproduction and Population Structure Litter-size (Mauritania, Tunisia and Egypt): one ($n = 32$). Reproductive chronology in Africa not known (data inconclusive); in Iraq, the reproductive chronology is restricted seasonal monoestry with mating in autumn, births in early Jun and lactation lasting ca. 40 days (Al-Robaee 1966). At 17°02'N in Mauritania, five pregnant ♀♀ were reported in mid-May (crown–rump length of embryos 7–13 mm); no data given for other months (Qumsiyeh & Schlitter 1981). In Egypt, 13 of 18 ♀♀ were pregnant, and five were adult but not pregnant, in late Apr to early May; no data for other months (Gaisler *et al.* 1972). In Burkina, young were observed in the wet season (mid-Jul); they were not yet independent and, based on their size, births were estimated to have occurred in late May to early Jun; adult-size attained in Nov (data collected Jun–Jan only; Koch-Weser 1984).

Predators and Diseases Regular, but minor, prey of Sooty Falcons *Falco concolor*, Lanner Falcons *Falco biarmicus*, Barn Owls *Tyto alba*, Pharaoh Eagle-owls *Bubo ascalaphus*, Spotted Eagle-owls *Bubo africanus* and Northern Long-eared Owls *Asio otus* (Booth 1961, Aulagnier 1989, Kowalski & Rzebik-Kowalska 1991, Benda *et al.* 2004d). Ectoparasites include a flea *Chiropteropsylla brockmani* (Siphonaptera: Ischnopsyllidae); bat-flies *Penicillidia senegalensis*, *Eucampsipoda hyrtlui* (Diptera: Nycteribiidae), *Brachytarsina kollari*, *Raymondia huberi*, *R. setosa* (Diptera: Streblidae); a tick *Carios boueti* (Acari: Argasidae); and mites *Hipposiderobia heteronycha* (Acari: Myobiidae) and *Opsonyssus striatus* (Acari: Gastronyssidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

GENUS *Cloeotis* Percival's Trident Bat

Cloeotis Thomas, 1901. Ann. Mag. Nat. Hist., ser. 7, 8: 28. Type species: *Cloeotis percivali* Thomas, 1901.

Cloeotis percivali.

Cloeotis is a monotypic genus endemic to Africa and known only from south-east Africa. Distinguished from other African genera of hipposiderids by the following combination of characters: posterior component of noseleaf with three tall, spear-like projections rising from the upper edge (i.e. trident-shaped) (Figure 65c); tail fully enclosed by interfemoral membrane, FA 32–39 mm. Furthermore, the posterior component of the noseleaf is pitted with deep cells (cf. *Asellia*) and the ears are short, very rounded and deep (Figure 67). Skull (Figure 67) with zygomatic arches not greatly expanded (c.f. *Triaenops*); rostrum very short with nasal swellings weakly developed; premaxillae not unusually thick; upper canine with secondary cusps. Dental formula $^{1123}/_{2123} = 30$.

The only species is *Cloeotis percivali*.

Meredith Happold

Figure 67. *Cloeotis percivali*. Flight membranes and bones of wing, hindlimb and tail. Dorso-frontal view of face showing the very deep, rounded ears (based on photo by N. Rautenbach in Mills & Hes 1997). Lateral view of skull (HZM 13.4765) and dorsal view of skull (RMCA RG 19243).

Cloeotis percivali PERCIVAL'S TRIDENT BAT (SHORT-EARED TRIDENT BAT)

Fr. Cléote de Percival; Ger. Percivals Kleinohr-Dreizackblattnase

Cloeotis percivali Thomas, 1901. Ann. Mag. Nat. Hist., ser. 8, 7: 28. Takaungu, north of Mombasa, Coast Province, Kenya.

Taxonomy Synonyms: *australis*. Subspecies: two of uncertain validity (see Geographic Variation). Chromosome number (South Africa): $2n = 40$; aFN not known (Rautenbach *et al.* 1993).

Description Very small microbat with noseleaf (posterior component with three tall projections); smallest African hipposiderid; dorsally grey to greyish-brown with orange-phase; tail almost fully enclosed by interfemoral membrane; FA: 31–39 mm. Sexes alike. Pelage soft, dense, silky; mid-dorsal hairs 7–8 mm. Dorsal pelage (grey-phase) slate-grey to medium or pale greyish-brown; hairs unicoloured. Face often paler (sometimes yellowish, sometimes off-white) with brown or grey around eyes, noseleaf and mouth. Ventral pelage white, off-white or yellowish-white; hairs dark brownish-grey or grey with white, off-white or yellowish tips. Orange-phase: dorsal pelage brown to bright brownish-orange becoming paler and more yellow on shoulders and head, with brown around eyes, noseleaf and mouth. Muzzle broad, short and rather flat. Ears separated, almost hidden by pelage, greyish-brown, comparatively and relatively short (25.4 [22–31]% of FA, $n = 46$), very rounded and deep with barely perceptible tip, giving each ear the appearance of a satellite dish. Noseleaf as in Figure 65c. Posterior component with a semi-circle of six cells (separated by moderately fleshy septa) around the outer margin, and four central cells arranged transversely across the middle. Each of the three projections arising from the posterior component is in line with one of the three septa separating the central cells: the three projections comprise the 'trident' referred to by the common name of this genus. Anterior component narrow, not concealing the broad, conspicuous lateral leaflets, anterior margin with deep, narrow median emargination. Nostrils deeply pocketed with well-defined lateral lappets. Wings and interfemoral membrane dark brown to greyish-brown. Calcar short, weak. Tail with last vertebra only protruding beyond interfemoral membrane; 64–91% of HB. Hindfoot small, delicate, with long claws. See also Hill (1982b).

Skull (Figure 67) very small and delicate; rostrum short and narrow; braincase relatively large. Zygomatic arches slender with a prominent jugal processes; zygomatic width > than mastoid breadth. No supraorbital ridges. Interorbital constriction very pronounced. Sagittal crest very low anteriorly, absent posteriorly. Cochlea slightly enlarged, their breadth ca. 1.5 times their distance apart. Upper incisor bicuspid. Upper canine slender with conspicuous posterior cusp and smaller anterior cusp. Anterior upper premolar fully displaced labially; canine and posterior premolar in contact or nearly so. M^3 not reduced, four ridges. Further craniodental details in Hill (1982b).

Geographic Variation Two subspecies are recognized by Koopman (1994) and Simmons (2005):

C. p. percivali: SE Kenya, NE Tanzania (but no localities given). FA: 31–32 mm, $n = 2$. Anterior lower premolar at least three-quarters the crown area of posterior premolar and more than half its height.

Cloeotis percivali

C. p. australis: S DR Congo to Botswana and Swaziland. FA: 32–39 mm, $n = 82$. Anterior lower premolar one half or less the crown area of posterior premolar and less than half its height.

These differences between the subspecies are slight, and the description of *australis* was based on only eight specimens. Hayman (1960b) noted an apparently constant colour difference between the northern and southern populations but at least one specimen from Zambia was the same colour as the holotype from Kenya (Hayman & Hill 1971). Therefore, subspecific distinction is probably not warranted.

Similar Species Four other hipposiderids in Africa have three vertical projections arising from the posterior component of the noseleaf:

Asellia tridens. Tail protruding up to 7 mm beyond interfemoral membrane. Larger (FA: 45–55 mm; CrnC: 16.5–19.3 mm). Only one upper premolar on each side; M^3 greatly reduced (only two ridges). Not sympatric.

A. patrizii. Tail protruding up to 5 mm beyond interfemoral membrane. Ears usually longer (12–16 mm). Only one upper premolar on each side; M^3 greatly reduced (only two ridges). In Africa, known only from Ethiopia and Eritrea.

Triaenops afer. Larger (FA: 49–60 mm; CrnC: 17.7–21.2 mm). Anterior component of noseleaf broad with a conspicuous process (hour-glass shaped in outline) arising from the sides of a deep median emargination. M^3 not greatly reduced (three ridges).

Distribution Endemic to Africa. Recorded mainly from the Zambezian Woodland BZ, but also found in some small parts of the Kalahari Desert, Highveld and Coastal Forest Mosaic BZs. In East Africa, known from the type locality just north of Mombasa in coastal Kenya and from Mafia I. (K. M. Howell pers. comm.). In south-central Africa and southern Africa, recorded disjunctly from SE DR Congo (Shinkolobwe, Katanga), Zambia (Kafue Gorge), SE Botswana (Kanye and Molopole areas), Mozambique (Tete District), Zimbabwe (six localities from the Kariba Dam in the north to Mutare in the east and Gwanda in the west), Swaziland (two localities) and South Africa (nine localities in the Northern, Mpumalanga and KwaZulu–Natal Provinces). References include Hayman 1960b, Koopman 1966, Smithers & Lobão Tello 1976, Smithers 1983, Monadjem 1998a.

Habitat Not much is known. Vegetation zones from which these bats have been recorded include undifferentiated woodland, wetter and drier miombo woodland and mopane woodland. In South Africa and Zimbabwe, many of the roosts are located in mixed woodland.

Abundance Uncertain. Since its description, only one other specimen has been taken from the type locality area (Kingdon 1974). Although the geographical range in south-central Africa and southern Africa is fairly wide, it is not known to occur there in great numbers.

Adaptations Aspect ratio very low; wing-loading very low. Based on wing morphology, probably capable of slow, manoeuvrable flight in dense vegetation. By day, recorded roosting in caves, service tunnels in dam walls, an underground irrigation canal in Zimbabwe, and disused mines; usually occupies the deepest, darkest parts where no light penetrates. Skull, lower jaw and dentition comparatively gracile; adapted for specializing on soft-bodied prey (Jacobs 2000).

Foraging and Food Foraging habits not known; wing morphology suggests foraging in dense vegetation (see Adaptations). Feeds almost exclusively on moths (Black 1979, Jacobs 2000).

Echolocation Call-shape CF/FM. CF-frequency 208–212 kHz; duty cycle high (Fenton & Fullard 1981, Taylor 1999a, Jacobs 2000). Fenton & Fullard (1981) and Jacobs (2000) suggest that the high frequency of its echolocation calls enables this species to prey more efficiently on moths. Moths respond to the sound of approaching bats by closing their wings and falling away from the bats' flight-path, but they hear best at frequencies between 20–50 kHz and are deaf to the high-frequency echolocation calls of *C. percivali*. Therefore this species can approach moths without eliciting their escape behaviour.

Social and Reproductive Behaviour Very little information. Roosts in groups (colonies) ranging in size from ca. 12 to a few hundred individuals. Hangs in loose groups in which adjacent individuals are

not in contact (i.e. not in tight clusters as indicated by Smithers 1983).

Reproduction and Population Structure Litter-size: one ($n = 6$). Reproductive chronology not known (data inconclusive). In Zimbabwe, pregnant ♀♀ were reported in Oct; no data published for other months (Smithers & Wilson 1979). At 27° 25' S (Jozini Dam, KwaZulu–Natal, South Africa), none of 3 adult ♀♀ was palpably pregnant in mid-Aug; 4 of 4 were pregnant or lactating in Nov (P. J. Taylor pers. comm.). At 25° 22' S (Sudwala, Mpumalanga Province, South Africa) 7 of 11 ♀♀ were pregnant and two were lactating in late Nov. These data indicate that some births occur in summer (Nov) and that adult ♀♀ are in reproductive synchrony, but it is not yet known if this species is monoestrous or polyestrous.

Predators, Parasites and Diseases Ectoparasites include a bug *Eoctenes intermedius* (Hemiptera: Polycetidae); bat-flies *Raymondia alulata*, *R. hardyi*, *R. seminuda* (Diptera: Streblidae); and mites *Eoctenes intermedius*, *Hipposiderobia cloeotis* (Acari: Myobiidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

However, very sensitive to disturbance by humans. Classified as 'specially protected' under the KwaZulu–Natal Nature Conservation Service Conservation Ordinance of 1999.

Measurements

Cloeotis percivali australis

FA: 34.1 (32–39) mm, $n = 82$

WS (c): 211 (196–228) mm, $n = 18^*$

TL: 65.8 (60–76) mm, $n = 61$

T: 29.1 (24–36) mm, $n = 81$

E: 8.8 (7–11) mm, $n = 81$

NL (length): 4.9 (4.6–5.2) mm, $n = 5$

NL (breadth, including lateral leaflets): 4.4 mm, $n = 1$

GENUS *Hipposideros*

Old World Leaf-nosed Bats

Hipposideros Gray, 1831. Zool. Misc. 1: 37. Type species: *Vespertilio speoris* Schneider, 1800.

Hipposideros cyclops.

Hipposideros gigas.

Hipposideros contains many more species than any other genus in the family Hipposideridae. Sixty-seven species are recognized by Simmons (2005), most of which occur in the eastern half of the Old World tropics and sub-tropics. Fourteen species occur in Africa. Distinguished from other genera of hipposiderids in Africa by the

following combination of characters. Posterior component of noseleaf roughly elliptical in shape and its upper margin is comparatively simple in outline (usually low-arched but subtriangular in one species) and does not have three triangular projections (although there is a club-shaped projection in some species) (Figure 68).

Tail more or less fully enclosed by interfemoral membrane (in some species, the last one or two vertebrae protrude). Skull with sagittal crest not developed primarily in the immediate postorbital region (cf. Rhinolophidae): the skull of *Hipposideros ruber* is illustrated as an example for the genus but there are some substantial inter-specific variations (Figure 69). Upper canine without enlarged secondary cusp. Dental formula $^{1123}/_{2123}$ in all African species except *H. megalotis* in which there is only one upper premolar on each side. African species range in size from very small to very large.

Figure 68. Noseleaves of selected African *Hipposideros* exemplifying the characters that are used to distinguish some of the species in this genus.

(a) Club-shaped process present (e.g. *H. cyclops*). (b) Outline of upper margin subtriangular; posterior component divided into four cells by three well-developed septa; internarial septum greatly enlarged into a prominent pad (e.g. *H. jonesi*). (c) Internarial septum moderately enlarged into a medium-sized pad; anterior component with deep median emargination (e.g. *H. curtus*). (d) Outline of upper margin low-arched; internarial septum moderately enlarged into comparatively small pad; two weakly-developed lateral leaflets present (e.g. *H. marisae*). (e) Posterior component divided into three cells by two well-defined septa; three well-developed lateral leaflets; anterior component without median emargination (e.g. *H. gigas*). (f) Posterior component not divided into cells by any well-developed vertical septa (e.g. *H. abae*). All noseleaves redrawn from Rosevear (1965).

Figure 69. *Hipposideros ruber*. Skull (partly based on Rosevear 1965).

Species in the genus have been allocated to species-groups by Tate (1941) and Hill (1963). Based on morphometric characters, Hill (1963) recognized seven species-groups, and most of the more recent researchers (e.g. Koopman 1994) have either accepted Hill's species-groups, or have made only minor changes. Do these species-groups reflect the phylogenetic history of the genus or convergent evolution? Bogdanowicz & Owen (1998) concluded, on the basis of cladistic analyses of craniodental characters and some body measurements, that some groups need to be redefined and revised and they also indicated that the genus *Hipposideros* does not comprise all of the descendants of an ancestor and most probably should be treated as a paraphyletic group. Based on evidence from fossils, Hand & Kirsch (1998) also concluded that some of Hill's species-groups do not reflect the phylogenetic history of the genus, and they too concluded that *Hipposideros* is probably paraphyletic. However, these two investigations have led to different conclusions about the relationships between the species. Because of this, Simmons (2005) has retained the traditional contents of *Hipposideros* pending a thorough revision, and has provisionally retained the contents of the species-groups according to the classification of Hill (1963) with some modifications, including the separation of four of the species in Hill's *diadema* group into a new group, the *commersoni* group. Here, the species-groups are as given by Simmons (2005).

Of the eight species-groups provisionally retained by Simmons (2005), five are represented in Africa as listed below:

megalotis group: one species – *H. megalotis*.

bicolor group: 34 species including *H. beatus*, *H. caffer*, *H. curtus*, *H. fuliginosus*, *H. jonesi*, *H. lamottei*, *H. marisae* and *H. ruber*. Support for this group as a whole is weak, but *H. curtus*, *H. jonesi* and *H. marisae* are evidently closely related.

cyclops group: eight species including *H. cyclops* and *H. camerunensis*, which are very closely related.

speoris group: two species, including *H. abae*.

commersoni group: four species, including *H. gigas* and *H. vittatus*.

The genus is a very old one, as indicated by the very large number of species, their diversification into so many species-groups, and the extent to which members of some of the species-groups are spread over the geographic range of the genus as a whole. Furthermore, according to Hill (1963), there are three distinct evolutionary trends within the genus: (1) exemplified by the *megalotis* and *bicolor* groups, towards small size, large ears and (usually) more complex noseleaves; (2) exemplified by the *cyclops* group, towards greatly developed noseleaves and much modification of the ears and the auditory region of the skull; (3) exemplified by the *speoris* group (and other groups extraliminally) towards greater size without extensive increase in the size and complexity of the ears and noseleaf, but with corresponding broadening of the skull. The genus is mainly confined to the tropics and sub-tropics, but species, including those in Africa, are found in diverse habitats and from high to low altitudes. In Africa, six species are found mainly in forest, five in both forest and savanna, one mainly in savanna, one in both savanna and arid habitats, and one in all of these habitats. Eight species are found in montane habitats but none is known only from montane habitats.

The 14 African species are distinguished mainly by the following characters:

Ears. Either well separated or joined by a low, inconspicuous frontal band.

Club-shaped process on the noseleaf. Either present (Figure 68a) or absent.

Internarial septum. Either enlarged by some specified degree into a pad (Figure 68b–d), or not enlarged.

Number of lateral leaflets on each side. One to four.

Frontal sac above the noseleaf. It can be absent, or present in one or both sexes in which case it can open horizontally (= transversely) or vertically (= longitudinally).

Position of the anterior upper premolar. It can be within the toothrow (so canine and posterior premolar are well separated), or fully displaced labially (so canine and posterior premolar are in contact) or partly displaced labially (so canine and posterior premolar are almost in contact). It is only the cingula of the canine and premolar which are in contact). The anterior upper premolar is absent in some species (Figure 70).

Posterior component of the noseleaf. It can be divided into cells by well-defined vertical septa (Figure 68a–e), or not divided by well-defined septa (Figure 68f).

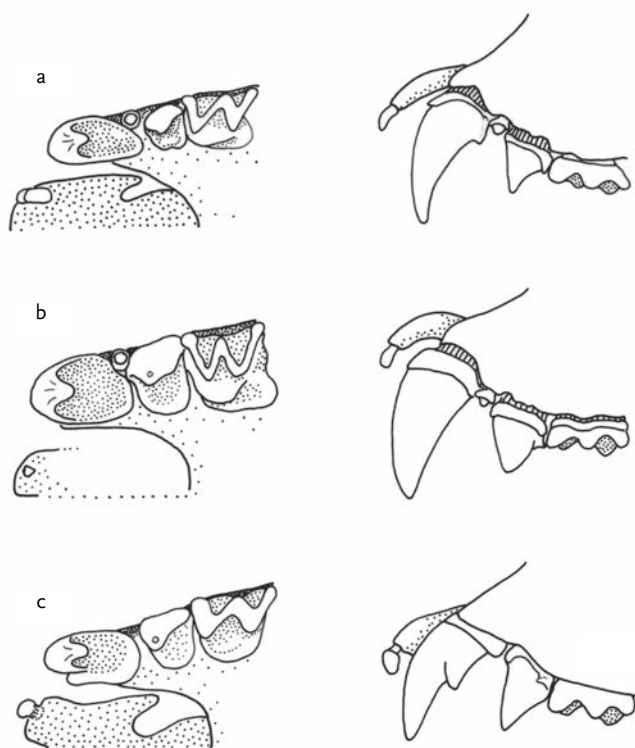

Figure 70. Variations in the sizes and positions of the upper premolars in *Hipposideros* occurring in Africa. *Left*: occlusal views of teeth on left side of upper jaw. *Right*: lateral views of labial side of the same teeth. The anterior upper premolar can be within the toothrow (e.g. *H. lamottei*: not illustrated), or (a) slightly displaced labially so canine and posterior premolar are well separated (e.g. *H. ruber*), (b) fully displaced labially so canine and posterior premolar are in contact (e.g. this specimen of *H. camerunensis*) or (c) absent, leaving a gap between the canine and the posterior premolar (e.g. *H. megalotis*). The outline of the premaxilla of the specimen of *H. camerunensis* was obscured by soft tissue.

Widest part of skull. It can be the zygomatic width (ZW) or the mastoid width (MW) or these dimensions can be equal (Figure 63). In some species (possibly those containing cryptic species) the widest part of the skull is variable.

Length of the forearm.

With these characters, all except seven species can be distinguished (see Table 15). Of these seven, the two largest species, *H. gigas* and *H. vittatus*, overlap in size but, where sympatric, *H. gigas* appears to be larger (see species profiles for further information). Some of the characters that enable the remaining five species (*H. beatus*, *H. caffer*, *H. ruber*, *H. fuliginosus* and *H. lamottei*) to be distinguished are given in the miscellaneous column of the table-key (Table 15) and additional characters are given in the Description and Similar Species sections of the species profiles. These include:

Length of the thumb claw. Measured from the top of the claw, where it emerges from the toe, to its tip, in a straight line (Figure 71).

Height of the thumb claw. Measured from the top to the bottom of the claw where it emerges from the toe (Figure 71).

Figure 71. Measurements of thumb claw used in profiles of some *Hipposideros* spp. L = length, H = height.

Figure 72. Differences in the rostral swellings of *Hipposideros caffer* and *H. ruber*. (a) Dorsal view, lit from above, of the anterior of the skull of *H. ruber* showing the position of the rostral swellings: li = lateral inflation; mpnc = median posterior nasal compartment. (b) Dorsal view of the rostral swellings of *H. caffer tephros*, backlit from below: the median posterior nasal compartment is narrow relative to the width of each of the lateral inflations (based on Kock 1969a). (c) Dorsal view of the rostral swellings of *H. ruber*, backlit from below: the median posterior nasal compartment (mpnc) is wide relative to the width of each of the lateral inflations (li) (based on Kock 1969).

Length of the phalanges of the third finger.

Length of the tibia (Tib).

Outline of the upper margin of the posterior component of the noseleaf. It can be low-arched (as in a flattened semi-circle, Figure 68a and c–e) or subtriangular (Figure 68b).

Width of the median posterior narial compartment of the nasal swelling relative to the width of each of the lateral inflations. This can be seen by back-lighting the skull (Figure 72).

Breadth of the cochleae relative to their distance apart (Figures 23 and 73).

The species are listed alphabetically, irrespective of the group to which they belong.

Table 15. Key to the African species in the genus *Hipposideros*. With these characters, all but seven species can be distinguished: the characters that enable *H. beatus*, *H. caffer*, *H. fuliginosus*, *H. lamottei* and *H. ruber* to be distinguished from each other are given in the profiles of these species. The widest part of the skull can be the zygomatic width (ZW) or the mastoid width (MW) or variable. Data taken from species profiles.

| Ears | Club-shaped processes | Internarial septum | Number of lateral leaflets | Frontal-sac (opening) | Position of anterior upper premolar (proximity of canine and posterior premolar) | |
|-----------|-----------------------|---------------------|----------------------------|---|--|--|
| Joined | Absent | Not enlarged | 0 | Absent | Absent
(In contact or separated) | |
| Separated | Present | Not enlarged | 2 | Both sexes
(Vertical) | Fully displaced
(In contact or almost so) | |
| Separated | Present | Not enlarged | 2 | Both sexes
(Vertical) | Fully displaced
(In contact or almost so) | |
| Separated | Absent | Greatly enlarged | 1 | Absent | Slightly displaced
(Well separated) | |
| Separated | Absent | Moderately enlarged | 2 (weakly developed) | Usually both sexes

(Well separated) | |
| Separated | Absent | Somewhat enlarged | 1 (rarely 2) | Both sexes
(Horizontal) | Slightly displaced
(Almost in contact) | |
| Separated | Absent | Not enlarged | 2 | Both sexes
(Horizontal) | Fully displaced
(In contact or almost so) | |
| Separated | Absent | Not enlarged | 2 | Both sexes, small in
♀ ♀
(Horizontal) | Slightly displaced
(Separated) | |
| Separated | Absent | Not enlarged | 2 | ♂ ♂ only
(Horizontal) | Slightly displaced
(Separated, usually well separated) | |
| Separated | Absent | Not enlarged | 2 | Both sexes
(n. d.) | Within tooththrow
(Well separated) | |
| Separated | Absent | Not enlarged | 2 | Absent | Somewhat displaced
(Almost in contact) | |
| Separated | Absent | Not enlarged | 3 | ♂ ♂ only
(Horizontal) | Fully displaced
(Almost in contact) | |
| Separated | Absent | Not enlarged | 3 | Both sexes
(Vertical) | Fully displaced
(In contact or almost so) | |
| Separated | Absent | Not enlarged | 3 or 4 | Both sexes
(Vertical) | Fully displaced
(In contact or almost so) | |

^aThe anterior upper premolar is said to be 'within tooththrow' if it lies in the middle of the tooththrow or is only slightly displaced labially, causing the canine and posterior upper premolar to be separated by a distinct gap.

^bPosterior component has three poorly defined septa.

^cThe median septum is comparatively weakly developed.

^dThe median septum is well defined, the lateral septa are very weak.

| | Posterior component divided into cells by well-defined septa (Number of septa) | FA mean (range) (mm) | Widest part of skull | Miscellaneous | Species |
|--|--|---|----------------------|--|------------------------|
| | No ^b | 36.8 (34–39) | MW | | <i>H. megalotis</i> |
| | Yes (3) | 75.9 (74–80) | ZW | Anteorbital foramen smaller; closed by narrow bar | <i>H. camerunensis</i> |
| | Yes (3) | ♂ ♂ 65.4 (61–75)
♀ ♀ 68.0 (59–74) | ZW | Anteorbital foramen larger; closed by moderately wide bar | <i>H. cyclops</i> |
| | Yes (3) ^c | 46.7 (44–50) | MW | Upper margin of posterior component of noseleaf subtriangular in outline | <i>H. jonesi</i> |
| | Yes (3) | 43.7 (42–47) | MW or equal | Upper margin of posterior component of noseleaf low-arched in outline | <i>H. curtus</i> |
| | Yes (3) | 40.6 (38–42) | Usually MW | Upper margin of posterior component of noseleaf low-arched in outline | <i>H. marisae</i> |
| | No | 43.7 (39–48) | ZW | Tib: 16.1 (15–19) mm | <i>H. beatus</i> |
| | No | 46.4 (42–52) | Variable | Tib: 20.0 (18–22) mm
Dorsal pelage greyish. Median posterior narial compartment of nasal swelling relatively narrow with wide lateral inflations | <i>H. caffer</i> |
| | No | 51.1 (47–55) | Variable | Tib: 21.4 (18–24) mm
Dorsal pelage brownish. Median posterior narial compartment of nasal swelling relatively wide with narrow lateral inflations | <i>H. ruber</i> |
| | No | 55.8 (55–57) | MW | Thumb claw length <2.5 mm
Third finger phalanges short, first: 12.5–14.3 mm, second: 10.5–12.1 mm | <i>H. lamottei</i> |
| | No | See profile for means (51–64) | ZW | Thumb claw length >3 mm
Third finger phalanges long, first: 14.3–18.7 mm, second: 17.8–21.9 mm | <i>H. fuliginosus</i> |
| | No | 59.3 (54–65) | ZW | No silver, white and brown markings | <i>H. abae</i> |
| | Yes (3) ^d | ♂ ♂ 101.5 (93–106)
♀ ♀ 93.9 (84–101) | ZW | Silver, white and brown markings. Smaller on average. Pelage shorter, not slightly woolly. Predominantly in savannas | <i>H. vittatus</i> |
| | Yes (3) ^d | ♂ ♂ 107.9 (100–124)
♀ ♀ 103.8 (95–116) | ZW | Silver, white and brown markings. Larger on average. Pelage longer, slightly woolly. Predominantly in forests | <i>H. gigas</i> |

Figure 73. Ventral views of skulls showing variations in the relative sizes of the cochleae in African *Hipposideros*. The cochleae are said to be not enlarged if the breadth of each one ranges from (a) slightly less than their distance apart (e.g. *H. abae*) to (b) slightly more than their distance apart (e.g. *H. gigas*). They are said to be (c) moderately enlarged if their breadth is 2–3 times their distance apart (e.g. *H. jonesi*) and (d) greatly enlarged if their breadth is 3–4 times their distance apart (e.g. *H. cyclops*).

Hipposideros abae ABA LEAF-NOSED BAT

Fr. Phyllorhine d'Aba; Ger. Aba-Rundblattnase

Hipposideros abae J. A. Allen, 1917. Bull. Am. Mus. Nat. Hist. 37: 432. Aba, Orientale, DR Congo.

Taxonomy Species-group: *speoris*; the only African representative of this group. Synonyms: none. Chromosome number: not known.

Description Medium-small microbat with noseleaf (posterior component roughly elliptical); blackish-brown with orange-phase; ears separated; noseleaf with three lateral leaflets on each side, no club-shaped processes and nostrils not concealed by an enlarged internarial septum. Sexes similar. Pelage fine, dense; mid-dorsal hairs 7–9 mm. Dorsal pelage (grey-phase) blackish-brown, paler on shoulders; hairs pale greyish-brown or smoke-grey with dark grey at base and blackish-brown at tip. Ventral pelage pale greyish-brown. Orange-phase: dorsal pelage bright orange or cinnamon-brown darkening to rusty-brown on middle of back (hairs pale orange-grey with cinnamon or rusty-brown at base and tip); ventral pelage paler especially on throat. In orange-phase, in DR Congo, ♀♀ are brighter than ♂♂ (Allen 1917a). Ears separated, comparatively and relatively short (29–39% of FA); brown, subtriangular, very broad; tip pointed with marked concavity in outer margin just below tip. Antitragus shallow with thickening at antitragal lobe. Noseleaf as in Figure 68f. Posterior component with well-developed transverse serrated supplementary structure; not divided into cells by vertical septa. No median club-shaped processes. Internarial septum weakly developed, not concealing nostrils. Three lateral leaflets on each side. Males with frontal sac, with horizontal opening and anterior cutaneous lip, enclosing stiff dark hairs; ♀♀ with tuft of hairs but no frontal sac. No anal sac. Wings and interfemoral membrane dark brown. Fifth metacarpal 84–90% of third metacarpal. Thumb moderately robust; claw length 2.8 (2.4–3.1) mm, claw height 1.2 (1.0–1.5) mm. Tibia 39–45% of FA. Tail 48–64% of HB.

Skull with zygomatic arches slender; zygomatic width > mastoid width (Figure 63b). Rostrum narrow and flattened. Sagittal crest low to moderate. Cochleae not enlarged, their breadth equal to their distance apart or a little less (Figure 73a). Upper incisor large, slightly bicuspid. Upper canine of moderate relative length (49 [47–53]% of C–M³, n = 11). Anterior upper premolar minute, displaced labially; canine and posterior premolar almost in contact. Anterior lower premolar one half the length and height of posterior premolar or slightly less. For further craniodental information, see Hill (1963).

Geographic Variation None recorded.

Similar Species Only two other African *Hipposideros* have three lateral leaflets on each side (Table 15, p. 370).

Hipposideros gigas. Much larger (FA: 95–124 mm; CrnC: 33.3–42.7 mm).

H. vittatus. Much larger (FA: 84–106; CrnC: 29.9–33.2 mm).

(Note: *H. beatus*, *H. caffer*, *H. fuliginosus* and *H. ruber* are otherwise fairly similar externally, but have only two lateral leaflets on each side).

*Hipposideros abae*

Distribution Endemic to Africa. Found in the Guinea Savanna BZ and Rainforest–Savanna Mosaic and, in West Africa and Uganda, marginally in the Rainforest BZ. Recorded, disjunctly, from Guinea-Bissau to S Sudan and N Uganda (but not in all countries). Most records are in isolated clusters. Mapped from country checklists (see order Chiroptera), other literature and museum records.

Habitat Typically found in *Isoberlinia* woodland and in mosaics of *Isoberlinia* woodland, lowland rainforest and secondary grassland (Rosevear 1965). In Sierra Leone and Uganda, occurs in lowland rainforest, suggesting that this species may be expanding its geographic range into this habitat (Grubb *et al.* 1998). In Ghana, found in thicket-like dry forest on Accra Plains (Decher 1997) as well as in *Isoberlinia* woodland north of the rainforest. In Garamba N. P., DR Congo, found in riverine forests and in nearby savanna habitats. Throughout geographic range, probably limited to habitats with caves or rocky outcrops (see below).

Abundance Uncertain. Locally abundant in some areas where caves are present, but not often collected (Lang & Chapin 1917b, Verschuren 1957, Rosevear 1965). Considered comparatively rare by Decher *et al.* (1997).

Adaptations By day, hangs freely in humid, draught-free day-roosts including caves, crevices, spaces under piles of boulders, and burrows (Verschuren 1957, Rosevear 1965). Day-roosts range in size from the dark recesses of caves to shallow grottos, holes between rocks, burrows of large mammals and the undersides of boulders

as long as these give protection from bright light and draughts. Sometimes roosts close to ground. The use of a subterranean bunker in Burkina was reported by Koch-Weser (1984). However, apparently *H. abae* differs from many other cave-dwelling species by only very rarely using man-made day-roosts (e.g. mines, buildings) or hollow trees. Caves opening into both forest and savanna habitats were utilized in Garamba N. P. (Verschuren 1957). Often shares day-roosts with other bats, including *Lissonycteris angolensis*, *Rhinolophus landeri*, *R. guineensis*, *Hipposideros caffer*, *H. jonesi* and *H. ruber* (Verschuren 1957, Koch-Weser 1984). Does not become torpid by day (Verschuren 1957, Rosevear 1965).

Foraging and Food No information. Has been netted over waterholes (Koopman *et al.* 1978), and sometimes flies into houses at night.

Echolocation No information.

Social and Reproductive Behaviour Typically roosts in small to very large groups (several hundreds) (Lang & Chapin 1917b, Verschuren 1957, Rosevear 1965), but the social structure of these groups is not known. The number of bats that roost together perhaps depends on the size of the day-roost. Individuals hang apart but near others. In Garamba N. P., occasionally found singly or in twos in caves shared with small groups of *H. ruber*, and also found in very large numbers with very large numbers of *H. ruber* (total number more than 1000). Individuals of both species intermingle and hang together. In Garamba N. P., they remain active and alert throughout the day, make a continuous clatter of sharp cries, and often make spontaneous flights within the day-roost. Occupancy of one cave varied from month to month, suggesting roost-fidelity is not high. In a sample of 229 bats taken from one cave in Apr, adult ♀♀ outnumbered adult ♂♂ by 2.2 : 1. Of the ♀♀ in this sample, two-thirds were lactating and the remainder reproductively inactive. Verschuren (1957) suggested that these data imply polygamy, but pair-formation cannot be ruled out. Segregation of the sexes during parturition and lactation does not seem to occur. The presence of insects in the stomachs of non-volant young suggests that adults bring prey to their young.

Reproduction and Population Structure Litter-size and reproductive chronology: uncertain. Monotoccy and restricted seasonal monoestry, with births in Mar, was reported for Cameroon and Uganda (Anciaux de Faveaux 1972) but both need confirmation. At 04°40'N (Garamba N. P., NE DR Congo) non-volant juveniles were recorded in Apr implying births in Mar (Verschuren 1957), but there are no data for other months.

Predators, Parasites and Diseases Ectoparasites include a bat-fly *Ascoapteron jonesi* (Diptera: Streblidae) and a mite *Psorergatoides hipposideros* (Acari: Psorergatidae) (Anciaux de Faveaux 1984). Rift Valley Fever virus has been isolated from *H. abae* (Calisher *et al.* 2006).

Conservation IUCN Category: Least Concern.

However, population trends and major threats are not known.

Hipposideros beatus BENITO LEAF-NOSED BAT

Fr. Phyllorhine naine; Ger. Benito-Rundblattnase

Hipposideros beatus K. Andersen, 1906. Ann. Mag. Nat. Hist., ser. 7, 17: 279. 15 miles (24 km) from Benito River, Rio Muni, Equatorial Guinea.

Taxonomy Species-group: *bicolor*. Considered closely related to *H. caffer* (Hill 1963). Synonyms: *maximus*. Subspecies: two. Chromosome number: not known.

Description Small to very small microbat with noseleaf (posterior component roughly elliptical); sepia brown, possibly without orange-phase; ears separated; noseleaf with two lateral leaflets on each side, no club-like processes and nostrils not concealed by internarial septum; frontal sac present in both sexes; thumb weakly developed; anterior upper premolar greatly reduced and fully displaced labially. Sexes similar. Pelage fine, fluffy; mid-dorsal hairs ca. 9 mm. Dorsal pelage

medium to dark sepia brown; hairs tricoloured, central third pale sepia brown, basal and terminal thirds medium to dark sepia brown. Orange-phase not known to occur. Ears separated, comparatively and relatively short (27–38% of FA), dark brown, triangular; tip shallowly pointed with concavity in outer margin just below tip. Antitragus with slight thickening at antitragal fold. Noseleaf approximately as in Figure 68f. Posterior component with well-developed transverse, serrated, supplementary structure on posterior face; not divided into cells by supporting septa; upper margin with low-arched outline. No club-like processes. Internarial septum not enlarged, not concealing nostrils. Two lateral leaflets on each side. Frontal sac present in both sexes; opening

through horizontal slit. Wings and interfemoral membrane dark brown. Thumb weakly developed (claw length 1.9 [1.4–2.3] mm, claw height 1.0 [0.9–1.2] mm). Tibia 36–44% of FA. Tail 47–72% of HB.

Skull short and broad; zygomatic arches slender; zygomatic width > mastoid width. Sagittal crest low. Cochleae not enlarged, their breadth equal to their distance apart or a little greater. Upper incisor slightly bicuspid. Upper canine relatively short (42 [38–48]% of C–M³, $n = 8$). Anterior upper premolar minute, fully displaced labially; canine and posterior premolar in contact or nearly so (Hill 1963). Anterior lower premolar a little more than half the length and height of the posterior lower premolar.

Geographic Variation Two subspecies are recognized by Hill (1963) and Koopman (1994):

H. b. beatus: Sierra Leone to Gabon. FA: 39–48 mm.

H. b. maximus: Central African Republic, extreme SW Sudan, NE DR Congo. FA: 43–48 mm.

Similar Species Four other African *Hipposideros* have the following combination of characters: ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum (Table 15, p. 370):

Hipposideros caffer. Tibia usually longer (19.2 [18–22] mm). Anterior upper premolar small but not greatly reduced, only slightly displaced labially; canine and posterior premolar not in contact. Echolocation CF-frequency (Côte d'Ivoire) 161 kHz.

H. ruber. FA longer (51.1 [47–55] mm). Tibia usually longer (21.4 [18–24] mm). Anterior upper premolar small but not greatly reduced, only slightly displaced labially; canine and posterior premolar not in contact (usually well separated).

H. fuliginosus. Much larger (FA [western population]: 55.0 [51–60] mm, FA [eastern population]: 62.6 [60–64] mm; CrnC [western population]: 19.9 [19.2–21.5] mm, CrnC [eastern population]: 23.2 [22.8–23.4] mm).

H. lamottei. Much larger (FA: 55.8 [55–57] mm; CrnC: 19.2 [18.9–19.6] mm).

(Note: *H. abae*, which is otherwise fairly similar externally, has three lateral leaflets on each side).

Distribution Endemic to Africa. Mostly recorded disjunctly from the Rainforest BZ (with some records in the Northern Rainforest–Savanna Mosaic, and one marginally in the Guinea Savanna BZ). Recorded from Sierra Leone to northern half of DR Congo. Subsequently recorded east of L. Albert, Uganda, by Thorn & Kerbis Peterhans (2009): not mapped. Not recorded from the Dahomey Gap, nor Bioko I. A record from Guinea-Bissau is erroneous (J. Fahr in Simmons 2005). A record from N Central African Republic (Schlitter *et al.* 1982) is rejected because, based on other records, the habitat is inappropriate and some craniodontal measurements of the specimen fall below the range exemplified by other specimens. A record from Kango, Chad (MNHN) has not been confirmed and has not been mapped because the habitat seems inappropriate. Mapped from country checklists (see order Chiroptera), other literature and museum records.

Hipposideros beatus

Habitat In West Africa, found in closed forests, degraded areas within the lowland rainforest, coastal woodlands and coastal scrub, and mosaics of thickets and grasslands, usually (possibly always) near rivers or swamps. In Gabon, not found anywhere except near rivers and swamps (Brosset 1966, 1982). In Garamba N. P., NE DR Congo, found in dense, humid riverine forests in Guinea Savanna BZ, but not found further south where these forests were much degraded (Verschuren 1957).

Abundance Uncertain. Rare in collections.

Adaptations Flies fast and powerfully with unceasing changes of direction and considerable manoeuvrability. Frequently glides short distances. Adept at flying in dense vegetation. By day, hangs freely in small day-roosts near the ground, which include hollow logs, spaces between piles of logs, small holes in trees, cavities under rocks, caverns eroded by streams, sheltered areas under exposed tree roots over water, holes in the ground and road culverts (Verschuren 1957, Rosevear 1965). One was found hanging from a grass-thatched roof (Grubb *et al.* 1998). Three were found in the partly flooded galleries of a mine in Gabon (Brosset 1966). In Gabon, one population roosted in abandoned traps (see Social and Reproductive Behaviour). When disturbed, individuals immediately fly from the day-roost into vegetation where they hide amongst leaves (Brosset 1966): therefore presumably they do not become torpid by day. Not known to roost in large caves, or to share day-roosts with other species of bats (Rosevear 1965). In Garamba N. P., the same roosts were occupied for several consecutive months, suggesting roost-fidelity is high (Verschuren 1957).

Foraging and Food Very little information. Forages in dense vegetation. Flying-ants and bugs were found in the stomach of one individual from Garamba N. P. (Verschuren 1957).

Echolocation Call-shape CF/FM. CF-frequency (*H. b. beatus* from Côte d'Ivoire) 139–147 kHz (J. Fahr & N. Ebigbo pers. comm.). CF-frequency (*H. b. maximus* from DR Congo, hand-held) 108 kHz (Novick 1958b).

Social and Reproductive Behaviour An impressive study of the social organization of *H. beatus* was made by Brosset (1982). He found that, on a small island in the Ivindo R., Gabon, seven of 22 abandoned traps originally built for catching Water Chevrotains *Hyemoschus aquaticus* were occupied by groups of *H. beatus*, which evidently preferred the traps to all other roost-sites available on the island. The traps were 90×90×150 cm in size, and all bats roosting inside could be captured; they were marked and censused at four-monthly intervals for three years. The bats were found to live in monogamous family groups comprised of one pair of adults with their young and one yearling of the preceding breeding season. These groups were sedentary and occupied small territories that saturated the island. Pairs maintained their associations from the beginning of one mating-period to the beginning of the next (Jul–Jun), but at the beginning of each mating-period, new pairs were formed through an exchange of mates in the population. Consequently, yearlings sometimes associated with a pair of adults that were not its parents. According to a few observations, ♀♀ reach sexual maturity when six months old; ♂♂ when at least one year old. In Garamba N. P., *H. beatus* was usually found roosting singly, in pairs and in groups of 3–4 but, on one occasion, a group of 12 was observed (Verschuren 1957). Another group, taken from a hollow tree in DR Congo, included two ♂♂, two ♀♀ and one juvenile (BMNH).

Reproduction and Population Structure Litter-size: one (n = 6; Brosset 1982). At 00°04'N (Makokou, Gabon), the reproductive chronology is restricted seasonal monoestry with mating at end of first wet season (Jun–Jul) and parturition in middle of second

wet season (Oct–Nov) (Brosset 1966, 1988). In contrast, at ca. 5°N (Garamba N. P., NE DR Congo) one lactating ♀ was observed in Apr and another post-lactating in May (no data for other months; Verschuren 1957).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Fairly widespread and no specific threats identified other than destruction of forest habitat.

Hipposideros caffer SUNDEVALL'S LEAF-NOSED BAT

Fr. Phyllorhine de Cafrerie; Ger. Sundevalls Rundblattnase

Hipposideros caffer (Sundevall, 1846). Öfv. Kongl. Svenska Vet.-Akad. Forhandl. Stockholm 3 (4): 118. Durban, South Africa.

Taxonomy Originally *Rhinolophus caffer*. Species-group: *bicolor*. Synonyms: *angolensis*, *aurantiaca*, *bicornis*, *braima*, *gracilis*, *nanus*, *tephrus*. Subspecies: four. Differences in skull morphology and echolocation calls suggest *H. caffer* includes more than one species. Since this profile was submitted, based on molecular evidence, *tephrus* Cabrera, 1906, has been restored to specific status by Vallo *et al.* (2007, 2008). Chromosome number (Kenya, Zimbabwe, South Africa): 2n = 32; aFN = 60 (Dulić & Mutere 1974, Peterson & Nagorsen 1975, Rautenbach *et al.* 1993).

Description Small microbat with noseleaf (posterior component roughly elliptical); greyish with orange-phase; ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum; frontal sac present in both sexes; thumb weakly developed with comparatively small claw and basal pad. Sexes alike. Pelage fluffy, dense, silky; mid-dorsal hairs ca. 9 mm. Dorsal pelage (grey-phase) grey to brownish-

grey; hairs tricoloured – cream to off-white with basal quarter pale greyish-brown and terminal quarter grey to brownish-grey. Ventral pelage slightly paler; hairs with basal half (or more) pale to medium greyish-brown and terminal half paler and sometimes with darker tips. Orange phase: dorsal pelage ranging from bright rusty-orange to golden-yellow. Ears comparatively short but relatively short to medium (24–38% of FA); broad, inner margin convex, outer margin convex becoming concave near tip; tip pointed. Antitragus shallow with slight thickening at antitragal fold. Noseleaf approximately as in Figure 68f. Posterior component with well-developed transverse serrated supplementary structure; not divided into cells by vertical septa; no club-shaped processes; internarial septum not concealing nostrils; anterior component without median emargination; two lateral leaflets on each side. Frontal sac present in both sexes but very small in ♀♀; opening horizontally. No anal sac. Wings and interfemoral membrane blackish-brown in both phases. Fifth metacarpal 86–92% of third metacarpal. Thumb, including claw

and basal pad, weakly developed (cf. *H. fuliginosus*), claw length 2.0 (1.6–2.7) mm, claw height 1.1 (0.9–1.3) mm. Tibia 39–46% of FA. Tail 49–65% of HB.

Skull short, broad; zygomatic arches slender anteriorly with a high jugal projection set far back; zygomatic width =, > or < than mastoid width (regional differences not yet resolved). Median posterior nasal compartment of rostral swelling relatively narrow with wide lateral inflations (Figure 72b) (cf. *H. ruber*); this can be seen in backlit skulls. Sagittal crest low. Cochleae not enlarged, their breadth equal to their distance apart, or a little greater. Upper incisor weakly bicuspid, outer cusp very weakly developed. Upper canine of medium relative length (48 [43–50]% of $C-M^3$, $n = 7$). Anterior upper premolar small or minute, only slightly displaced labially; canine and posterior premolar not in contact. M^3-M^3 greater than $C-M^3$.

Geographical Variation Koopman (1994) recognizes four subspecies:

H. c. tephros: Morocco and dry sub-Saharan belt from Mauritania and Guinea to Sudan, but see Taxonomy.

H. c. angolensis: Ghana, Gabon, Angola, Namibia.

H. c. nanus: NE DR Congo.

H. c. caffer: Remainder of geographic range.

Similar Species Four other African *Hipposideros* have the following combination of characters: ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum (Table 15, p. 370):

Hipposideros ruber. Usually larger, especially where sympatric (FA: 51.1 [47–55] mm; CrnC: 19.1 [17.8–20.3] mm). Median posterior nasal component of rostral swelling relatively wide with narrow lateral inflations. Dorsal pelage (grey-phase) usually more brown than grey.

H. beatus. Tibia usually shorter (16.1 [15–19] mm). Anterior upper premolar greatly reduced and fully displaced labially; canine and posterior premolar in contact or almost so.

H. fuliginosus. Much larger (FA [western population]: 55.0 [51–60] mm, FA [eastern population]: 62.6 [60–64] mm; CrnC [western population]: 19.9 [19.2–21.5] mm, CrnC [eastern population]: 23.2 [22.8–23.4] mm).

H. lamottei. Much larger (FA: 55.8 [55–57] mm; CrnC: 19.2 [18.9–19.6] mm).

(Note: *H. abae*, which is otherwise fairly similar externally, has three lateral leaflets on each side.)

Distribution In Africa, widely but disjunctly distributed in all sub-Saharan biotic zones, except the Highveld and South-West Cape BZs, but not distributed in all parts of any of these biotic zones, and there are comparatively few records in the Rainforest and South-West Arid BZs and in the Horn of Africa. There are isolated populations in the Mediterranean Coastal BZ in NW Africa (Aulagnier & Thévenot 1986). Recorded from Morocco (Aulagnier & Thévenot 1986) and from most countries south of the Sahara; also Mafia I. (Kock & Stanley 2009), Pemba I. and Zanzibar I. There is a recent record (not mapped) from Terjît, Wilaya Adrar, Mauritania (20° 15.578' N,

Hipposideros caffer

13° 05.854' W) (Padial & Ibáñez 2005). Extraliminally: SW Arabian Peninsula.

Habitat Most records are in woodland savannas; less commonly recorded in more arid regions and in forests. In Mauritania, one specimen was recorded near a small relict stream in the Adrar Mts where some other plant and animal species of the Sahel have been found (Padial & Ibáñez 2005). In South Africa, Zimbabwe and Botswana the geographic range appears restricted to regions receiving more than 500 mm rain (Rautenbach 1982), and in the more arid parts of the range, they may be restricted to river courses (Taylor 2000).

Abundance Apparently common to very abundant in optimum habitats where day-roosts are available, but seldom mist-netted. One cave in Gabon contained ca. 500,000 (Brosset 1968) but possibly many represented *H. ruber*. One cave in Nigeria probably contained ca. 1000 (Menzies 1973). In Malawi, Zimbabwe and South Africa, colonies of several hundreds have been reported, but much smaller colonies also occur, at least in South Africa (Smithers & Wilson 1979, Rautenbach 1982, Taylor, P. 1998, R. T. F. Bernard pers. obs.).

Adaptations Aspect ratio low; wing-loading very low (Aldridge & Rautenbach 1987). Able to fly slowly or rapidly, and with agility and manoeuvrability. Can take off from ground and hover briefly. Turns by banking and by stalling-and-twisting. Day-roosts include caves, small rock cavities and fissures, mine-adits, culverts under roads, abandoned buildings, roofs of houses, wells and hollow trees (Smithers 1983). Hangs freely from ceilings or rafters. In KwaZulu-Natal (South Africa), roosts at back of mine-adits and caves where microclimate is most stable (R. T. F. Bernard unpubl.). Sometimes shares roosts with other species, including *Rhinolophus landeri*, *R. clivosus*, *Nycteris thebaica*, *Myotis tricolor* and *Miniopterus schreibersii*. Does not hibernate, but becomes torpid for short periods during particularly cold weather (Bernard & Meester 1982). In dry country,

often mist-netted over water and observed sipping water while in flight; suggests dependence on this resource (Smithers 1983).

Foraging and Food Forages by slow-hawking and by gleaning from branches and the ground. Commonly feeds on swarms of insects attracted to electric lights. A study of the foraging behaviour of free-living bats under controlled conditions (in Zimbabwe) in which the prey was either motionless, fluttering and flying, or fluttering but not flying, and in which the bats could use echolocation and/or visual cues or neither, indicated that they attack fluttering targets that are flying as well as those sitting on smooth or cluttered solid backgrounds, and that they use only Doppler-shifted echoes to detect their targets (Bell & Fenton 1984 as *H. ruber*). Some light-tagged individuals foraged by slow-hawking 1–10 m over water; others flew along the face of an escarpment and gleaned from rock surfaces and vegetation; one foraged ca. 1 m high over open ground and made frequent dives to the ground. Individuals attracted to swarms of insects around an electric ultraviolet light fed primarily on moths, and attacked and captured those of wingchord 5–60 mm (wingchord = length of leading edge of forewing). However, analysis of wings discarded by these bats showed that they fed mostly on moths of wingchord 10–25 mm, irrespective of species. The majority of insects attracted to the light were usually moths of this size and, although on certain nights beetles comprised ca. 80% of the total attracted insects, moths were still the chosen prey. Moths comprised 88% of insects identified in faeces. Bowie *et al.* (1999) also found that moths comprised most (80%) of the diet of *H. caffer* in South Africa. However, they occasionally feed on other insects including lacewings, caddis-flies, orthopterans, termites and beetles (Fenton *et al.* 1977, Findley & Black 1983, Bell & Fenton 1984 as *H. ruber*).

Echolocation Call-shape CF/FM. CF-frequency varies in different localities as follows:

Gambia: 138 ± 8.25 kHz (4 ♂♂) and 149 ± 4.35 kHz (2 ♀♀) (Jones *et al.* 1993).

Côte d'Ivoire (Taï N. P.): 161 kHz (Fahr *et al.* 2003).

E DR Congo (Irangi): 154–157 kHz (Heller 1992).

Uganda (Entebbe): 136.7–152.5 kHz (14 bats, not sexed) (Pye 1972).

Kenya (Shimoni): 146.5–159.7 kHz (12 bats not sexed) (Pye 1972).

Zimbabwe: 141.5 ± 2.7 kHz (Fenton 1986).

South Africa (Kruger N. P.): 138 kHz (25 bats, not sexed) (Aldridge & Rautenbach 1987); (Luvuvhu) 145.4 ± 2.5 kHz (Fenton 1986); (Jozini Dam) 145 ± 0.2 kHz (14 bats, not sexed) (Taylor 1999a).

(Note: mean \pm 1 S.D. in some cases).

The data suggest that the CF-frequency can vary by as much as ca. 16 kHz within a single population, and by as much as ca. 24 kHz across the continent. Pye (1972) found some evidence of a bimodal distribution of CF-frequency and a silent interval when bats were recorded in groups but not when isolated, and tentatively proposed a functional interpretation of the silent interval in terms of Doppler spreading. The data from Gambia (Jones *et al.* 1993) suggest that ♀♀ may use higher CF-frequency than ♂♂, but apparently this has not been investigated elsewhere. Another explanation for the variation between different localities is that more than one species is involved.

Social and Reproductive Behaviour Brosset (1966) and Kock (1969a) reported some foraging areas being used only by ♂♂, but the segregation of sexes during foraging needs further investigation. Roosts singly or in groups of two to several hundreds, possibly as many as 500,000 (see Abundance). Neighbours hang apart (separated by a few centimetres). Sex ratio in day-roosts changes seasonally as a consequence of the formation of maternity colonies (Menzies 1973, R. T. F. Bernard pers. obs.); at one cave in Nigeria, the ♂♂ apparently dispersed, leaving the ♀♀ behind to give birth and suckle (Menzies 1973). (Note: although Menzies [1973] identified his bats with *H. caffer guineensis* [now considered a subspecies of *H. ruber*], on basis of FA, GLS and habitat, they are more likely to represent *H. caffer*.) In Zimbabwe, a group of banded bats comprised of one adult ♂, seven lactating ♀♀ and their young, occupied a hollow baobab *Adansonia* from late Dec to late Jan (Bell 1987). The stability and composition of this group suggests a harem mating system. During this time, a large number of non-resident *H. caffer*, and other species, attempted to gain access to this roost, implying that the availability of day-roosts for *H. caffer* in this locality is limited, and suggesting that resource-defence (*sensu* Emlen & Oring 1977) is the basis for harem associations in this species, but more data are needed to confirm this and to show if harems are maintained in larger roosts where it may be more difficult to defend particular sites.

Reproduction and Population Structure Litter-size: one. Throughout Africa, the reproductive chronology is restricted seasonal monoestry (Menzies 1973, O'Shea & Vaughan 1980, Bernard & Meester 1982). At 10° 20' N (Shagunu, Nigeria), births occur at beginning of the unimodal wet season (ca. Apr) (Menzies 1973); in South Africa, births occur in early summer (early Dec). At equatorial latitudes, perhaps some populations exhibit a boreal cycle with births in Mar while other have an austral cycle with births in Oct (Brosset 1968), but the possibility that the different cycles were exemplified by different species (*H. caffer* and *H. ruber*) needs investigation. At equatorial latitudes (where the identification of material needs confirmation), gestation is ca. 100 days (Brosset 1968) and this increases to 150 days at 10° N (Shagunu, Nigeria; Menzies 1973) as a result of delayed implantation, and 210 days at 29° S (KwaZulu–Natal, South Africa; Bernard & Meester 1982) as a result of three months of retarded embryonic development during winter.

Predators, Parasites and Diseases Ectoparasites include a flea *Lagaropsylla consularis* (Siphonaptera: Ischnopsyllidae); 29 species of bat-flies (Diptera: Nycteribiidae, Streblidae); a tick *Carios vespertilionis* (Acari: Argasidae); and 25 species of mites (Acari: Spinturnicidae, Macronyssidae, Myobiidae, Trombiculidae, Leeuwenhoekidae, Psorergatidae, Chirodiscidae) (Anciaux de Faveaux 1984). Chikungunya and Rift Valley Fever viruses have been isolated from *H. caffer* (Bres & Chambon 1964, Calisher *et al.* 2006).

Conservation IUCN Category: Least Concern.

Hipposideros camerunensis CAMEROON LEAF-NOSED BAT

Fr. Phyllorhine du Cameroun; Ger. Kamerun-Rundblattnase

Hipposideros camerunensis Eisentraut, 1956. Zool. Jahrb. Abt. Syst. Oekol. Geogr. Tiere 84: 526. Near Buea, Cameroon.

Taxonomy Species-group: *cyclops*. *Hipposideros camerunensis* and *H. cyclops* are closely related and considered the most primitive members of this group. The disjunction between the population in Cameroon and the population(s) in E DR Congo and W Kenya raises the possibility that these populations might be specifically, or subspecifically, distinct (see Conservation), but as yet there is no confirmatory evidence. Synonyms: none. Chromosome number: not known.

Description Medium-large microbat with noseleaf (posterior component roughly elliptical); blackish-brown; pelage woolly and frosted; noseleaf with two median club-shaped processes; FA: 75.9 (74–80) mm. Not easily distinguished from *H. cyclops*. Sexes apparently similar but data are limited. Pelage dense, soft, woolly; mid-dorsal hairs 13–15 mm. Dorsal pelage blackish-brown with pale creamy-brown frosting; hairs dark blackish-brown with curly, creamy-brown tip. Dorsal pelage extending along proximal half of forearm. Ventral pelage slightly paler; frosting less conspicuous. No orange-phase. Ears well separated, comparatively long but of medium relative length (40–50% of FA), narrow, dark brown, inner margin convex, outer margin convex becoming concave near tip, tip narrowly pointed. Antitragus smoothly convex. Noseleaf similar to that of *H. cyclops* (Figure 68a). Posterior component divided into four cells by three vertical septa, and with a club-like process arising from middle of posterior edge. A second median club-shaped process arises from the central component. Internarial septum weakly developed, not concealing nostrils. Two well-developed lateral leaflets on each side, the lower pair continuous with the posterior component. Frontal sac present and prominent in both sexes; opening vertically. Wings and interfemoral membrane slightly translucent dark brown; skin on forearm, digits and tibia much paler reddish-brown. Fifth metacarpal 93–99% of third metacarpal. Tibia 44–52% of FA. Hindfoot 18–22 mm. Tail 33–46% of HB. As in *H. cyclops*, ♂♂ have a (glandular?) sac between penis and anus, opening posteriorly just in front of anus. This anal sac can be everted to reveal a conspicuous tuft of stiff, reddish-brown hairs. Females lack this anal sac but have a patch of bare skin with scattered long and stiff hairs near the vagina.

Skull large, robust, elongate with broad rostrum and broadened braincase; zygomatic arches massive; zygomatic width > mastoid width. Rostrum broad. Sagittal crest low. Anteorbital foramen comparatively small (cf. *H. cyclops*), closed by narrow bar. Cochleae

greatly enlarged, their breadth 3–4 times their distance apart. Upper incisor slightly bicuspid. Upper canine massive but relatively short (42 [40–44]% of C–M³, n = 7). Anterior upper premolar small, fully displaced labially; canine and posterior premolar in contact or almost so. Anterior lower premolar ca. one-quarter the length and ca. half the height or slightly less of the posterior premolar. Further craniodental information in Hill (1963).

Geographic Variation None recorded.

Similar Species Only one other African *Hipposideros* has two median club-shaped processes on the noseleaf, and frosted blackish-brown woolly pelage (Table 15, p. 370):

Hipposideros cyclops. Usually smaller (FA ♂♂: 65.4 [61–75] mm, FA ♀♀: 68.0 [59–74]; CrnC: 28.2 [26.3–30.0] mm). Anteorbital foramen larger and closed by a moderately wide bar.

Hipposideros camerunensis

Distribution Endemic to Africa. Known only, very disjunctly, from the Afromontane–Afroalpine BZ (Cameroon) (Eisentraut 1956), the Rainforest BZ (E DR Congo) (Hayman *et al.* 1966), and from two localities in the Eastern Rainforest–Savanna Mosaic in W Kenya (Schlitter *et al.* 1986). Subsequently also recorded from Budongo (00°45'N, 31°36'E) and Itama (00°57'S, 29°42'E), Uganda, by Thorn & Kerbis Peterhans (2009): not mapped.

Habitat Afromontane forests at 1200–1400 m on Mt Cameroon; degraded afromontane forest with undergrowth of *Acanthus arboreus* and *Brillantaisia* in North Nandi Forest, Kenya; intermediate evergreen forest in Kakamega Forest, Kenya; and lowland rainforest at Shabunda, DR Congo.

Abundance Uncertain. Rare in collections.

Adaptations Based on measurements of a dried museum specimen, aspect ratio is low and wing-loading is high or very high, but this needs confirmation from unpreserved specimens. If correct, flight is predicted to be fast, agile and energetically expensive, and manoeuvrability is probably poor. Day-roosts include caves and hollow trees (Eisentraut 1973a). One individual was caught in the bottom shelf of a mist-net (Schlitter *et al.* 1986), suggesting that this species sometimes forages near the ground.

Foraging and Food Predictably forages by fly-catching, as does *H. cyclops* and *H. vittatus* (see species profiles). Diet not known, but the massiveness of the zygomatic arches suggests that *H. camerunensis* can eat hard-shelled insects.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Twelve ♀♀ were pregnant in Oct in Cameroon (Eisentraut 1963). No other information.

Conservation IUCN Category: Data Deficient.

The possibility that the records comprise more than one species has been debated by the IUCN assessors and evaluators: because of habitat loss, the Mt Cameroon population is possibly a threatened endemic species.

Hipposideros curtus SHORT-TAILED LEAF-NOSED BAT

Fr. Phyllorhine à queue courte; Ger. Kurzschnauz-Rundblattnase

Hipposideros curtus G. M. Allen, 1921. Rev. Zool. Bot. Afr. 9: 194. Sakbayeme, Cameroon.

Taxonomy Species-group: *bicolor*. Synonyms: *sandersoni*. Subspecies: none. Chromosome number: not known.

Description Small to very small microbat with noseleaf (posterior component roughly elliptical); sepia brown; ears large and separated; noseleaf with enlarged internarial septum, which partly conceals the nostrils, and two lateral leaflets on each side; frontal sac usually present in both sexes. Sexes similar. Pelage long, silky, fluffy. Dorsal pelage sepia brown; hairs buff with sepia brown at base and at tip. Ventral pelage same as dorsal pelage, or slightly paler. Orange-phase: no information. Ears separated, comparatively short but of medium relative length (35–49% of FA), rounded (length and breadth almost equal), tip bluntly pointed with sharp concavity in outer margin just below tip; each ear with 11 internal folds (n = 1). Antitragus well developed with small fold. Noseleaf as in Figure 68c. Posterior component not elongated; divided into four cells by three vertical septa; upper margin with low-arched outline. No club-like processes. Anterior component broad, almost covering muzzle. Internarial septum pad-like and moderately enlarged, forming a

longitudinally oval disc (longer than broad), which partly conceals the nostrils. Two weakly-developed lateral leaflets on each side. Frontal sac usually present in both sexes (sometimes absent in ♀♀); opening horizontally. Wings and interfemoral membrane blackish-brown. Fifth metacarpal 89–109% of third metacarpal. Tibia 37–49% of FA. Tail 35–51% of HB.

Skull delicate, short and broad; zygomatic arches moderate; zygomatic width = mastoid width or slightly less. Sagittal crest low. Cochleae not enlarged, their breadth ca. equal to their distance apart or a little greater. Upper incisor slightly bicuspid. Upper canine relatively short (42 [38–48]% of C–M³, n = 4). Anterior upper premolar small, slightly displaced labially, canine and posterior premolar well separated. Further details in Hill (1963).

Geographic Variation None recorded.

Similar Species Only two other African *Hipposideros* have a noseleaf with the internarial septum enlarged (Table 15, p. 370):

Hipposideros jonesi. Margin of posterior component elongated, subtriangular in outline; internarial septum larger, broader than long; one long, well-developed lateral leaflet on each side; no frontal sac. Ears usually larger (21–28 mm) and ca. 50% of FA.

H. marisae. Usually smaller (FA: 40.6 [38–42] mm; CrnC: 15.6 [15.4–15.8] mm). Ears 15–17 mm; no antitragal fold. Internarial septum less enlarged, oval disc smaller; usually only one, rudimentary, lateral leaflet on each side. Frontal sac present in both sexes.

Distribution Endemic to Africa. As yet, known only from the Rainforest BZ in Cameroon (where recorded from at least seven localities) and from Equatorial Guinea (both mainland and Bioko I.) (Allen 1921, Sanderson 1939, Aellen 1952, Perret & Aellen 1956, Eisentraut 1973a, J. Juste pers. comm.).

Habitat Apparently restricted to lowland rainforest.

Abundance Uncertain. Very rare in collections.

Remarks Very little is known about this species (Rosevear 1965). Its flight is described as sluggish in comparison with that of *H. caffer* (Sanderson 1939). One individual foraged with numerous *H. caffer* in the verandah of a house. One was caught over a stream (Sanderson 1939). A small colony, which varied in size according to season, roosted in a shelter formed by big rocks; others have been found under a boulder in a forest (Perret & Aellen 1956). Also roosts in caves (Eisentraut 1964).

Conservation IUCN Category: Vulnerable.

Some of the few known roosts have disappeared and habitat is being lost as a result of selective logging, clear-cutting and other human activities. Population trend: declining.

Hipposideros cyclops CYCLOPS LEAF-NOSED BAT

Fr. Phyllorhine cyclope; Ger. Zyklopen-Rundblattnase

Hipposideros cyclops (Temminck, 1853). Esquisses Zool. sur la Côte de Guinée, p. 75. Boutry River, Ghana.

Taxonomy Originally *Phyllorhina cyclops*. Species-group: *cyclops*. Synonyms: *langi*, *micaceus*. Subspecies: none recognized. Chromosome number: not known.

Description Medium-sized microbat with noseleaf (posterior component roughly elliptical); blackish-brown with woolly, frosted pelage; ears separated; noseleaf with two median club-shaped processes; FA: 66.6 (59–75) mm. Not easily distinguished from *H. camerunensis*. Females significantly larger and heavier than ♂♂ in most body measurements. Pelage dense, soft, woolly; extending along proximal half of forearm; mid-dorsal hairs 11–13 mm (18–

19 mm at high altitudes). Dorsal pelage blackish-brown with white or silvery frosting; hairs blackish-brown with curly, white or silvery tip. Head greyish-brown with darker eye-rings. Ventral pelage paler than dorsal pelage with less conspicuous frosting. No orange-phase. Ears separated, comparatively medium to long but of medium relative length (42–53% of FA), narrow, medium to dark brown, inner margin convex, outer margin convex becoming concave near tip, tip narrowly pointed. Eyes comparatively large. Noseleaf as in Figure 68a. Posterior component divided into four cells by three vertical septa, and with a club-shaped process arising from middle of posterior edge. A second median club-shaped process arises

from the central component above the nostrils. Internarial septum weakly developed, not concealing nostrils. Two well-developed lateral leaflets on each side, the lower pair continuous with the base of the posterior component. Frontal sac present and prominent in both sexes; opens vertically. It is lined with long, stiff, white hairs that form a conspicuous tuft when the sac is everted. At each side of the frontal sac there is a glandular patch or shallow sac. Wing and interfemoral membranes blackish-brown; skin on forearm, digits and tibia much paler reddish-brown. Fifth metacarpal 96 (92–100)% of third metacarpal. Tibia 42–52% of FA. Tail 45–49% of HB. Males have a (glandular?) sac lined with long, stiff, reddish-brown hairs, between penis and anus, opening posteriorly just in front of anus (Figure 74). Females lack this anal sac but have a patch of bare skin with scattered long and stiff hairs near the vagina.

Skull robust, elongate with broad rostrum and elongated braincase; zygomatic arches massive; zygomatic width much greater than mastoid width. Rostrum broad. Sagittal crest low. Infraorbital (= anteorbital) foramen large, rounded and closed by a moderately wide bar (cf. *H. camerunensis*). Cochleae greatly enlarged, their breadth four times their distance apart (Hill 1963) (Figure 73d). Upper incisor slightly bicuspid. Upper canine powerful, relatively short (42 [37–46]% of C–M³, n = 8). Anterior upper premolar very small, fully displaced labially; canine and posterior premolar in contact. Anterior lower premolar ca. one-third to half the length and half the height of the posterior premolar.

Geographic Variation Variable throughout geographic range although no subspecies are currently recognized. Populations from drier habitats have significantly longer forearms than those from wetter habitats as exemplified (in Côte d'Ivoire) by bats from the Guinea Savanna BZ (Comoé N. P.) with FA: 67.1 (62–72) mm (n = 45) compared to those from the Rainforest BZ (Taï N. P.) with FA: 65.2 (62–70) mm (n = 28). Specimens from E DR Congo, W Uganda and N Burundi seem to attain larger dimensions, but sample-size is limited.

Similar Species Only one other African *Hipposideros* has two median club-shaped processes on the noseleaf, and frosted blackish-brown woolly pelage (Table 15, p. 370):

Hipposideros camerunensis. Usually larger (FA: 75.9 [74–80] mm; CrnC: 30.2 [29.2–31.5] mm). Infraorbital foramen smaller and closed by a narrow bar. Not known west of 9° E, but geographical ranges overlap from Cameroon to Kenya.

Distribution Endemic to Africa. Recorded from the Rainforest BZ (Western, West Central and East Central Regions), the adjacent Northern and Eastern Rainforest–Savanna Mosaics and Afromontane–Afroalpine BZ, with an apparently isolated population in the Eastern Arc Mts and the Coastal Forest Mosaic BZ of Kenya and Tanzania. Recorded, somewhat disjunctly, from Senegal to coastal Kenya and Tanzania. Gaps in Guinea and Nigeria might reflect insufficient sampling. There are very few records from the central Congo Basin and it remains to be established if the species ranges throughout the entire Congolian rainforest zone. The record from Bamingui-Bangoran N. P., Central African Republic, appears to be very isolated.

Figure 74. Pubic region of adult ♂ *Hipposideros cyclops* showing (a) the anal sac in its invaginated state and (b) in its everted state. (c) Pubic region of adult ♀ *H. cyclops* showing the patch of bare skin with scattered long, stiff hairs near the vagina. All based on Allen (1917a). The pubic region is the same in *H. camerunensis*.

Hipposideros cyclops

Habitat Recorded mainly from lowland rainforest but also from coastal forest, montane forest, swamp forest and mangroves vegetation zones. Also extends far into the Rainforest–Savanna Mosaic, and into the Guinea Savanna BZ where sufficiently large relict forests and gallery forests are present. Although mostly recorded in undisturbed forest, also found in secondary forest, highly degraded areas, and converted habitats such as cocoa and rubber plantations (Lang & Chapin 1917b, Jeffrey 1975, Fedden &

Macleod 1986, Schlitter *et al.* 1986, Juste & Ibáñez 1994, USNM records). Highest reported altitudes are 1000–1200 m on Mt Nimba (Liberia), 1100 m on Mt Kupé (Cameroon) (Hill 1968, Wolton *et al.* 1982) and 1950 m in Kibira N. P., Burundi (FMNH).

Abundance Widespread and comparatively abundant in suitable habitat. The most frequently captured hipposiderid in Comoé N. P., Côte d'Ivoire, and the second most frequently captured hipposiderid in Tai N. P. Local distribution and abundance is probably determined by the availability of suitable day-roosts.

Adaptations Flight moderately fast, manoeuvrability poor; energetic cost of flight probably high (J. Fahr & K. Soer unpubl.). By day, most often found roosting in spacious hollow trunks of standing trees, including *Borassus*-palms, *Ceiba pentandra*, *Cola cordifolia*, *Cordia* sp., *Hallea stipulosa*, *Klainedoxa gabonensis*, *Macaranga* sp., *Pseudospondias microcarpa*, *Ricnodendron heudelotii* and *Terminalia superba* (Decher & Fahr 2005a). Very occasionally found inside fallen logs, old wells and disused mines, and once found in a belfry. Never found in hollow *Cynometra megalophylla* in Comoé N. P. although this tree is very abundant in gallery forests and its hollow trunks seem suitable. Often shares day-roosts with other bats (*Lissonycteris angolensis*, *Nycteris arge*, *N. major*, *Rhinolophus alcyone*, *R. landeri*), anomalures (*Idiurus macrotis*, *Anomalurus* spp.), African Dormice (Gliridae) and Tullberg's Soft-furred Mouse *Praomys tullbergi* (Decher & Fahr 2005a). The recapture rate was 17% ($n = 35$) in Tai N. P. and 20% ($n = 59$) in Comoé N. P. (J. Fahr unpubl.). Most individuals were recaptured up to one year after marking, and two individuals were recaptured after three years. All were recaptured less than 400 m from the initial site, most less than 250 m, suggesting that home-ranges are very small (several ha) and that site-fidelity is unusually high. The eyes of *H. cyclops* are large in comparison with those of most other African hipposiderids, suggesting that vision plays a more important role in orientation than in other species of bats. Together with its sister species *H. camerunensis*, it is possibly the only African *Hipposideros* that does not have an orange-phase. The frosted pelage perhaps helps to camouflage these bats while they are exposed to predators during perch-hunting (see Foraging).

Foraging and Food Insectivorous. Forages by fly-catching and, very rarely, by slow-hawking. Usually forages not far from the ground or vegetation. Median foraging height in Côte d'Ivoire (as determined by captures in mist-nets set 0–25 m above ground) was 1.9 (0.4–23.6) m, $n = 91$, J. Fahr unpubl.). Most individuals were caught 1–8 m above ground, but six were caught between 13.5 and 23.6 m. They are specialized fly-catchers and rarely fly except when commuting from day-roosts to feeding areas, flying from one perch to another, or attacking prey. They emerge from their day-roosts comparatively early (18:00–18:30h) and fly to perches, such as tree trunks, branches and twigs, which are usually 2–6 m above ground. There they rotate from side to side while echolocating and scanning the surroundings for flying insects. Detected insects are captured in flight, and either carried back to the perch, or to the day-roost, where they are divested of their wings and other hard parts, and then consumed. Verschuren (1957) analysed discarded wings and other remains collected in Garamba N. P., NE DR Congo, and found predominantly hawk-moths (Sphingidae) and cicadas but also owl-flies (Neuroptera: Ascalaphidae),

flat-bugs (Heteroptera: Aradidae), wasps (Hymenoptera: Eumenidae) and beetles (Coleoptera: Scarabaeidae, Elateridae). Additionally, Verschuren (1957) found bark-lice (Psocoptera), moth-flies (Diptera: Psychodidae) and ants (Hymenoptera: Formicidae) in stomach contents. In Comoé N. P. these bats predominantly took hawk-moths, cicadas and beetles, but also ant-lions (Neuroptera: Myrmeleontidae), grasshoppers and crickets (Orthoptera: Acrididae, Gryllidae) and winged male driver-ants (Hymenoptera: Formicidae: *Dorylus* spp.) (K. Soer & J. Fahr unpubl.).

Echolocation Call-shape CF/FM. CF-frequency in resting bats (Côte d'Ivoire) 59.7 (58.4–60.8) kHz (J. Fahr & N. Ebigo unpubl.). The CF-frequency of 101–109 kHz given by Novick (1958b) is erroneous and possibly the result of the recording equipment at that time (J. Fahr unpubl.).

Social and Reproductive Behaviour Roosts singly or in small to medium-sized groups comprised of 1–3 ♂♂ and several ♀♀ (Aellen 1952, Verschuren 1957, Fedden & Macleod 1986, J. Fahr unpubl.). The largest group found in Comoé N. P. consisted of 18 individuals (not sexed). Lang & Chapin (1917b) and Eisentraut (1956) reported group-sizes of 12 individuals. The mean ratio of ♂♂ to ♀♀ in colonies was 1 : 1.8 in Garamba N. P. (Verschuren 1957). Individuals roosting singly are mostly ♂♂. The frontal sac in both sexes, and the anal sac in ♂♂, are likely to play an important role in olfactory communication although the specific function is not known. The anal sac, when everted, emits a very strong, almost pungent odour. Not yet known if the odour is produced by glands or by bacterial fermentation of excretions. Young are not left in day-roosts during the night but are carried by their mothers, even during perch-hunting (J. Fahr pers. obs.).

Reproduction and Population Structure Litter-size: one. Reproductive chronology uncertain. In the Northern Rainforest–Savanna Mosaic (Fintonia, NW Sierra Leone; Comoé N. P., NE Côte d'Ivoire; Garamba N. P., NE DR Congo), 11 of 14 adult ♀♀ were pregnant, two were lactating and one was neither pregnant nor lactating in Feb–Apr; 10 of 15 ♀♀ were lactating and five were neither pregnant nor lactating in May–Jun; none of 18 ♀♀ was pregnant or lactating in Oct–Nov; no data for other months (Verschuren 1957, J. Fahr unpubl., USNM). According to Verschuren (1957), in Garamba N. P., ♀♀ are in fairly close reproductive synchrony; births take place in mid-Mar, lactation ends in mid-May, and there is no evidence of a second parturition season; young are born with a FA ca. 25 mm. In the Rainforest BZ of Côte d'Ivoire, none of 18 adult ♀♀ was pregnant or lactating in Jan–Feb; 1 of 11 was pregnant, one was lactating and nine were neither pregnant nor lactating in Mar; none of 3 ♀♀ was pregnant or lactating in Jun; 8 of 14 ♀♀ were pregnant and six were neither pregnant nor lactating in Jul–Oct; 1 of 1 was lactating in Dec; no data for other months (J. Fahr unpubl., CM, MHNG, ROM, SMF, USNM). None of the females was found simultaneously lactating and pregnant ($n = 34$). These data are not conclusive but they are compatible with restricted seasonal monoestry in the Rainforest–Savanna Mosaic (with lactation coinciding with the onset of the wet season), and extended seasonal monoestry in the Rainforest BZ (with the majority of ♀♀ giving birth towards the end of the wet season).

The ratio of ♂♂ to ♀♀ as determined by captures with mist-nets (excluding recaptures) in Comoé N. P. was 1 : 0.6 (n = 55); in Taï N. P., it was 1 : 0.7 (n = 29; J. Fahr unpubl.).

Predators, Parasites and Diseases Remains of one individual were found in scats of an unidentified small carnivore (probably genet *Genetta* sp.) in Central African Republic (Hutterer & Ray 1997). Ectoparasites include bat-flies *Raymondia brachyphysa*, *R. intermedia* (Diptera: Streblidae) and a mite *Steatonyssus hipposideros* (Acari: Macronyssidae) (Jobling 1956). In Taï N. P., 23% of the individuals (n = 35) were heavily infested with unidentified, bright orange mites (J. Fahr unpubl.).

Conservation IUCN Category: Least Concern.

Probably most threatened by destruction of suitable day-roosts and direct exploitation therein.

Hipposideros fuliginosus SOOTY LEAF-NOSED BAT (TEMMINCK'S LEAF-NOSED BAT)

Fr. Phyllorhine fuligineuse; Ger. Temmincks Rundblattnase

Hipposideros fuliginosus (Temminck, 1853). Esquisses Zool. sur la Côte de Guinée, p. 77. Ashanti Land, Ghana (type locality 'Côte de Guinée' restricted by Jentink 1887, 1888).

Taxonomy Originally *Phyllorhina fuliginosa*. Species-group: *bicolor*. Synonyms: currently none. Subspecies: currently none recognized (but see Geographic Variation). Often confused with *Hipposideros ruber*, *H. caffer*, *H. lamottei* and *H. abae*. Andersen (1906) recognized the confused taxonomy of this bat and pointed out some of the specific characters for a diagnosis of the species. The analyses of Koopman (1989) and Koopman *et al.* (1995) again confused the situation by focusing entirely on measurements of the skull while not considering external measurements, proportions and characters. The following account is therefore largely based on specimens examined by the author, disregarding most of the published records because of the difficulties in identifying this species. Chromosome number: not known.

Description Small to medium-sized microbat with noseleaf (posterior component roughly elliptical); dark brown with orange-phase; ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum; no frontal sac; thumb well developed with comparatively large claw and basal pad. Sexes similar. Pelage slightly coarser than in *H. caffer* and *H. ruber*. Dorsal pelage (grey-phase) dark brown. Ventral pelage similar but paler. Ears separated; comparatively and relatively short (30–31% of FA), broad, triangular and pointed with slight concavity in outer margin just below tip: 11 internal folds. Antitragus with slight fold. Posterior component of noseleaf not divided into cells by vertical septa; upper margin with low-arched outline. Behind the upper margin, there is a low to well-developed transverse supplementary structure, which is sometimes smooth

(Hill 1963) and sometimes more or less serrated (Koopman *et al.* 1995); the variability renders this character of little value as a means of distinguishing *H. fuliginosus* from *H. ruber* and *H. caffer* in which the structure is serrated (Koopman *et al.* 1995). No club-shaped processes; internarial septum not concealing nostrils; two lateral leaflets on each side. Frontal sac absent in both sexes (but sometimes there is a patch of bare skin). No anal sac. Wings and interfemoral membrane blackish-brown. Thumb and claw comparatively long and powerful, claw length >3 mm, claw height >1.2 mm; pad at base of thumb well developed. Fifth metacarpal 84–92% of third metacarpal. Third finger with comparatively long phalanges (first phalanx 14.3–18.7 mm, 28–31% of FA; second phalanx 17.8–21.9 mm, 33–37% of FA) (cf. *H. lamottei*). Tibia comparatively short, and 38–39% of FA (cf. *H. lamottei*). Tail comparatively short, and 45–49% of HB.

Skull robust; zygomatic arches slender; zygomatic width > mastoid width. CrnC relatively long (36.3 [35–40]% of FA, n = 83) (cf. *H. lamottei*). Sagittal crest prominent in specimens from the eastern population, much less so in specimens from the western population (see below). Cochleae not enlarged, their breadth only a little greater than their distance apart. Upper incisor slightly bicuspid. Upper canine of medium relative length (48 [44–51]% of C–M³, n = 3). Anterior upper premolar small, somewhat displaced labially; canine and posterior premolar almost in contact. Anterior lower premolar ca. half the height and length of the posterior premolar.

Geographic Variation Although no subspecies have been described, there are two morphometrically distinct populations –

a western population in Guinea to Cameroon and Gabon, and an eastern population known from only a few specimens from DR Congo, Central African Republic and Uganda. Eastern specimens are much heavier, and larger in both body and craniodental measurements (see Measurements) and have proportionally broader zygomata. They probably represent an undescribed taxon closely related to *H. fuliginosus*.

Similar Species Four other African *Hipposideros* have the following combination of characters: ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum (Table 15, p. 370):

Hipposideros ruber. Smaller on average in all measurements (FA: 51.1 [47–55] mm; CrnC: 19.1 [17.8–20.3] mm). Thumb, claw and basal pad smaller (claw length <3 mm). Frontal sac usually present in ♂♂ but not in ♀♀. Echolocation CF-frequency higher (132–144 kHz).

H. lamottei. Skull relatively smaller (CrnC: 34–35% of FA), and usually also comparatively smaller (CrnC: 19.2 [18.9–19.6] mm; C–M³: 6.6 [6.4–6.7] mm); zygomatic width < mastoid width; dentition much weaker. Frontal sac present in both sexes. Ears relatively shorter (25–29% of FA). Thumb, claw and basal pad much smaller and less powerful (claw length <2.5 mm). Third finger with shorter phalanges (first 12.5–14.3 mm; second 10.5–12.1 mm). Tibia relatively longer (41–42% of FA).

H. beatus. Much smaller (FA: 43.7 [39–48] mm; CrnC: 16.8 [16.1–18.1] mm).

H. caffer. Much smaller (FA: 46.4 [42–52] mm; CrnC: 17.2 [16.1–18.3] mm).

(Note: *H. abae*, which is otherwise fairly similar externally, has three lateral leaflets on each side.)

Distribution Endemic to Africa. Recorded, disjunctly, from the Rainforest BZ (Western, West Central and Eastern Regions), Afromontane–Afroalpine BZ and Northern and Eastern Rainforest–Savanna Mosaics. Known from ca. 25 localities in West Africa (Sierra Leone, Guinea, Liberia, Côte d'Ivoire, Ghana, SE Nigeria) and west-central Africa (Cameroon and Gabon). Also, five isolated records from the central Congo Basin, from the Ituri/Albertine Rift area in E DR Congo and W Uganda, and from S Central African Republic (Pépélou, MHNG). Two records from Gabon (Booué [00°06'S, 11°56'E], Kango [00°09'N, 10°08'E]) are included based on the description and measurements (FA: 54–57 mm) of the specimens (Malbrant & Maclatchy 1949). A record from Gaba R., Ethiopia, published as *H. fuliginosus* by Lagen *et al.* (1974), probably represents an unnamed species resembling *H. lamottei* (J. Fahr unpubl.). A record from Ngombe, DR Congo, by Hayman *et al.* (1966), needs to be re-examined and is not included here.

Habitat Largely restricted to Rainforest BZ and mostly recorded from wetter and drier types of lowland rainforest although also recorded from coastal forest and mangroves vegetation zones. In Guinea, recorded from ravine forests within montane grassland at 1350 m altitude (Fahr & Ebigo 2003) and in Kalinzu Forest, Uganda, from sub-montane forest at 1500 m altitude (LACM). Extends along riverine forests into drier areas such as Fintonia (Sierra Leone) and Comoé N. P. (Côte d'Ivoire) in the Northern Rainforest–Savanna Mosaic.

Abundance Widespread but localized and comparatively rare.

Adaptations Wings broad and rounded; flight very manoeuvrable. By day, has been found roosting in the hollow trunks of standing trees. Sometimes shares roosts with *H. ruber* (Hayman 1945, Aellen 1952 as *H. caffer*). Hayman (1945), when comparing *H. fuliginosus* with *H. abae*, suggested that the presence of the frontal sac in ♂♂ might be under seasonal influence and of little diagnostic value. However, the frontal sac was consistently absent in adult ♂♂ of *H. fuliginosus* taken throughout the year and therefore it is of diagnostic value.

Foraging and Food In contrast to larger hipposiderids, forages by slow-hawking and does not seem to forage by fly-catching. Median foraging height in Côte d'Ivoire (as determined by captures in mist-nets set 0–25 m above ground) was 1.7 (0.4–2.6) m (n = 22), indicating that this bat forages mainly in the understorey of the forest, in densely cluttered situations (J. Fahr unpubl.). Diet not known in detail, but likely to be medium- to large-sized flying insects such as moths and beetles.

Echolocation Call-shape CF/FM. CF-frequency in resting bats from Côte d'Ivoire: 113–121 kHz (18 bats; J. Fahr & N. Ebigo unpubl.). CF-frequency of six hand-held bats from Guinea was 120–123 kHz (Fahr & Ebigo 2003). CF-frequency can help to distinguish *H. fuliginosus* from *H. ruber*.

Social and Reproductive Behaviour Has been recorded roosting in groups of 2–39 individuals (Hayman 1945, Aellen 1952, USNM). In Cameroon, one group included two adult ♂♂, five adult ♀♀ and five young (Aellen 1952). A collection from Oda, Ghana,

apparently taken from the same hollow tree, comprised at least 30 ♂♂ and nine ♀♀ (USNM).

Reproduction and Population Structure Litter-size: not known. Reproductive chronology not known. At 05° 50' N (Taï N. P., Côte d'Ivoire), 1 of 1 ♀ was pregnant in Feb; 5 of 5 ♀♀ were lactating in Mar; 3 of 3 were neither lactating nor palpably pregnant in late Aug and Sep; no data for other months. At 08° 45' N (Comoé N. P., Côte d'Ivoire), 4 of 8 were lactating and four were neither lactating nor palpably pregnant in May, and 2 of 2 were neither lactating nor palpably pregnant in Oct; no data for other months. These data, although inconclusive, are compatible with seasonal monoestry.

Predators, Parasites and Diseases Ectoparasites include a bat fly *Raymondia seminuda* (Diptera: Streblidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

Population trend inferred to be declining because of large-scale loss and degradation of habitats within the distribution of this species, particularly in West Africa.

Hipposideros gigas GIANT LEAF-NOSED BAT

Fr. Phyllorhine géante; Ger. Riesen-Rundblattnase

Hipposideros gigas (Wagner, 1845). Arch. Naturgesch. 11 (1): 148. Benguela, Angola.

Taxonomy Originally *Rhinolophus gigas*. Species-group: *commersoni* with *H. vittatus* (Africa) and *H. thomensis* (São Tomé). Synonyms: *gambiensis*, *niangarae* and probably *viegasi*. Based on FA length (♂ 107 mm, ♀ 103 mm), *viegasi* is more likely to be a synonym of *H. gigas* than *H. vittatus* and therefore, following Hayman & Hill (1971) it is provisionally retained here in *H. gigas*. In contrast, Simmons (2005) has followed a suggestion by J. Fahr (pers. comm.) that *viegasi* is probably a synonym of *H. vittatus*. Subspecies: none currently recognized. Formerly often considered to be a subspecies of *H. commersoni* (e.g. Hill 1963, Koopman 1993) but differences in morphology and echolocation calls indicate *H. gigas* and also *H. vittatus* are distinct species (Pye 1972, McWilliam 1982) and *Hipposideros commersoni* is now considered restricted to Madagascar. In some parts of Africa, *H. gigas* is now known to occur sympatrically with *H. vittatus*, which, as *H. c. marungensis*, was also formerly considered a subspecies of *H. commersoni*. Consequently, the distributions of both *H. gigas* and *H. vittatus* are expected to be considerably more extensive than pre-2005 records indicate and, furthermore, it might be some time before pre-2005 information attributed to *H. commersoni* in Africa,

Hipposideros gigas

H. c. gigas and *H. c. marungensis* is reallocated to its correct species. Chromosome number: not known.

Description Very large microbat with noseleaf (posterior component roughly elliptical); the largest African hipposiderid and the largest African microbat; medium to dark brown with silver, white and brown markings and an orange-phase; ears separated; noseleaf with three or four lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum. Not easily distinguished morphometrically from *H. vittatus*. Sexes similar in colour; ♂♂ on average larger than ♀♀. Pelage slightly woolly, not sparse on rump; mid-dorsal hairs ca. 8 mm. Dorsal pelage (grey-phase) ranging geographically from medium to dark brown, with silvery frosting on nape, rump and next to wings; head paler; hairs unicoloured or with silvery-grey at tip. Ventral pelage medium grey to pale brown, with silvery frosting. Armpits pure white or yellow, usually surrounded by dark brown. Orange-phase: dorsal pelage bright dark rusty-brown to bright orange; ventral pelage golden rusty-brown. Ears separated, comparatively medium to long but relatively short (23–37% of FA); brown; triangular, tapering to bluntly pointed tip with little or no concavity in outer margin below tip. Antitragus shallow. Noseleaf as in Figure 68e. Posterior component divided into four shallow cells by three weak, vertical septa. No club-shaped processes. Internarial septum not enlarged, not concealing nostrils. Three or four lateral leaflets on each side. Frontal sac present in both sexes; opening vertically. No anal sac. Wings and interfemoral membrane brown. Fifth metacarpal 95–100% of third metacarpal. Tibia 42 (39–44)% of FA. Tail 30 (23–37)% of HB.

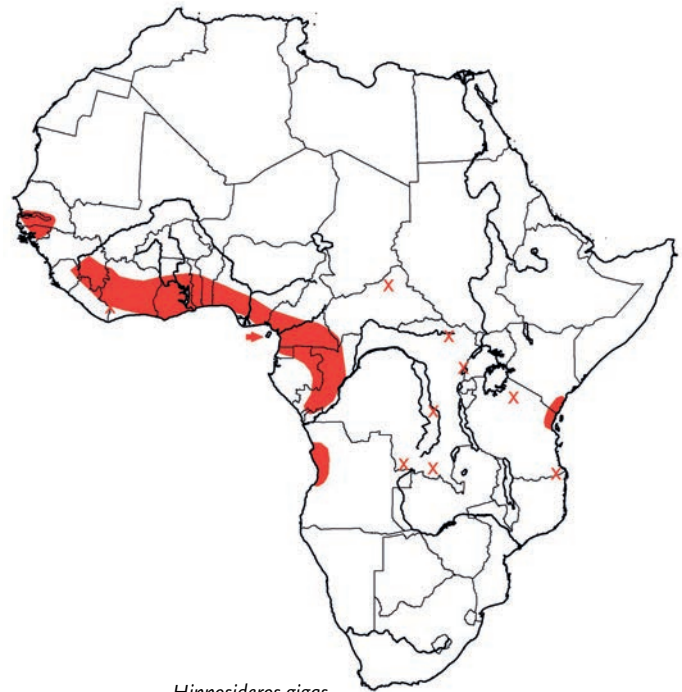

Skull large with broad rostrum; zygomatic arches massive; zygomatic width > mastoid width. Sagittal crest greatly developed (especially in ♂♂) and merging with the supraorbital ridges. Cochleae not enlarged, their breadth only a little greater than their distance apart. Upper incisor slightly bicuspid. Upper canine relatively long (53 [49–59]% of C–M³, n = 13). Anterior upper premolar very small, displaced labially; canine and posterior premolar in contact or nearly so. Anterior lower premolar half the length and height of posterior premolar or slightly less.

Geographic Variation Uncertain. No subspecies recognized by Simmons (2005).

Similar Species Only one other African *Hipposideros* has FA >79 mm, and no club-shaped processes on noseleaf (Table 15, p. 370):

Hipposideros vittatus. Smaller on average (FA [♂♂]: 101.5 [93–106] mm, FA [♀♀]: 93.9 [84–101] mm). Pelage shorter, not slightly woolly. Echolocation CF-frequency 61–66 kHz (depending on locality). Predominantly a savanna species. In at least some areas of sympatry, FA measurements of adults of same sex do not overlap – e.g. in coastal Kenya, *H. vittatus* FA (♂♂): 90–108 mm; FA (♀♀): 85–98 mm (cf. *H. gigas* FA [♂♂]: 109–122 mm; FA [♀♀]: 105–116 mm) (A. N. McWilliam pers. comm.).

Distribution Endemic to Africa. Recorded mainly from the Sudan Savanna, Guinea Savanna, Rainforest and Coastal Forest Mosaic BZs, the Rainforest–Savanna Mosaics and the Zambebian

Hipposideros gigas

Woodland BZ. Previously thought to occur only in western side of Africa, from Senegal to southern Central African Republic and southwards to Namibia (including Bioko I.) (Koopman 1994), but now known to occur in E DR Congo, Kenya and Tanzania, and perhaps occurs even further afield (see Taxonomy). Based on habitat, specimens referred to *gigas* from N Burkina (Koopman *et al.* 1978) and N Togo (De Vree *et al.* 1969) probably represent *H. vittatus* and are tentatively mapped for that species, but no measurements are available for these specimens. Based on FA length, specimens identified with *H. commersoni* from three localities in N Nigeria (BMNH, Bergmans 1977b), and one identified with *H. commersoni gigas* from Central African Republic (Schlitter *et al.* 1982), are more likely to represent *H. vittatus* and are mapped for that species. Currently not considered to occur in Namibia (Simmons 2005) or in S Angola (J. Fahr pers. comm.). Mapped from localities of museum and published specimens whose identification (if not already assigned to *gigas*) could be verified by FA and GLS measurements.

Habitat Lowland rainforest habitats, East African coastal forests and wetter types of woodland savanna. The presence of suitable caves and hollow trees in which to roost is likely to be more important than the type of vegetation (Grubb *et al.* 1998).

Abundance Uncertain; very common in some localities.

Adaptations Aspect ratio, wing-loading and flight characteristics not known but likely to be fairly similar to those of *H. vittatus*. By day, usually hangs, free or in contact, in caves and large hollow trees, but sometimes roosts singly in foliage (Rosevear 1965). Easily disturbed by humans, and may desert a day-roost after a single disturbance. Does not become torpid during the day, and does not hibernate (Brosset 1969). Heavy fat deposits have been reported in Guinea-Bissau by Monard (1939, as *H. gigas viegasi*) and at the end of the first wet season (Jun) in Gabon (Brosset 1966). In Kenya, *H. gigas*

migrates from the coast inland in Oct and again in Mar, to take advantage of the earlier and more predictable arrival inland of the two wet seasons (McWilliam 1982).

Foraging and Food Foraging: no information. Diet is mainly large beetles but individuals sometimes take large Orthoptera (Brosset 1969), and gorge themselves seasonally on winged termites (Lang & Chapin 1917b).

Echolocation Call-shape CF/FM. CF-frequency (Shimoni, Kenya) 54 (51–56) kHz (17 bats; A. N. McWilliam pers comm.). Pye (1972) observed a bimodal distribution of CF-frequencies in a colony of '*H. commersoni*' inhabiting caves at Shimoni: the CF-frequencies were ca. 56 kHz and ca. 66 kHz with a silent interval of 8 kHz. It is now known that *H. gigas* emits the 56 kHz calls, and that *H. vittatus* emits the ca. 66 kHz calls.

Social and Reproductive Behaviour In Gabon, roosts in colonies of 50–400 (Brosset 1966, Brosset & Saint Girons 1980). Parturient ♀♀ segregate for only a few days (Brosset 1969).

Reproduction and Population Structure Litter-size: one. At 0–1°N in NE Gabon the reproductive chronology is restricted seasonal monoestrus with copulation in May during the Apr–May peak in rainfall, and births in Oct during the Sep–Dec peak in rainfall (Brosset 1969). The young grow rapidly, fly at 30–35 days, reach adult-size at ca. two months and sexual maturity after two years. At 04° 39'S (Shimoni, coastal Kenya), copulation occurs in the long dry season (Jul–Aug), and births during the short wet season (Nov) (McWilliam 1982).

Predators, Parasites and Diseases Anciaux de Faveaux (1984) lists parasites of '*H. commersoni*' in Africa, but it is not certain which have been recorded from *H. gigas*, and which from *H. vittatus*.

Conservation IUCN Category: Least Concern.

In Gabon, colonies are periodically drastically reduced by humans who eat these bats (Brosset 1966), but overall population trend not known. Potentially also threatened by selective logging and clear cutting.

Hipposideros jonesi JONES'S LEAF-NOSED BAT

Fr. Phyllorhine de Jones; Ger. Jones' Rundblattnase

Hipposideros jonesi Hayman, 1947. Ann. Mag. Nat. Hist. ser. 11, 14: 71. Makeni, Sierra Leone.

Taxonomy Species-group: *bicolor*. Synonyms: none. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component very roughly elliptical but upper margin more angular than in other *Hipposideros*); greyish-brown with orange-phase; ears very large and separated; noseleaf with enlarged internarial septum, which partly conceals the nostrils, and one lateral leaflet on each side; frontal sac absent in both sexes. Sexes similar. Pelage fine, dense, silky; mid-dorsal hairs 10–11 mm. Dorsal pelage (grey-phase) greyish-brown to dirty-brown; hairs dark grey with grey at tip. Ventral pelage paler; hairs grey with pale grey or pale brown to whitish tip. Orange-phase: dorsal pelage tawny-orange to cinnamon. Ears separated; comparatively short to medium, but relatively medium to long (45–60% of FA), broad, subtriangular, pointed with only a

faint concavity in outer margin below tip; each ear with 11 internal folds. Antitragus with distinct fold. Noseleaf as in Figure 68b, longer than broad. Posterior component conspicuously elongated, divided into four cells by two prominent lateral septa and one weak middle septum. Upper margin strongly curved and subtriangular in outline. No club-like processes. Anterior component hairy and broad, covering muzzle. Internarial septum pad-like and greatly enlarged, forming a transversely oval disc (broader than long), which partly conceals the nostrils. One well-developed and long lateral leaflet on each side. No frontal sac. No anal sac. Wings and interfemoral membrane dark grey. Fifth metacarpal 96 (93–100)% of third metacarpal. Thumb comparatively weak. Tibia 46 (43–48)% of FA. Tail 48 (34–53)% of HB.

Skull delicate, elongated, with narrow, pointed rostrum and relatively broad, high braincase; zygomatic arches slender; zygomatic

width < mastoid width (Figure 63c). Sagittal crest low. Cochleae moderately enlarged, their breadth 2–3 times their distance apart (Figure 73c). Upper incisors slightly bicuspid. Upper canines relatively short (38 [34–42]% of C–M³). Anterior upper premolar small, slightly displaced labially; canine and posterior premolar well separated. Anterior lower premolar ca. half the length and height of posterior lower premolar.

Geographic Variation Hayman (1964) documented extensive geographic variation and ascribed this to a morphological cline, with western specimens (Sierra Leone) being significantly smaller than eastern specimens (Ghana). However, specimens from even further east (C Nigeria) are smaller than those from Ghana and populations from Côte d'Ivoire, Mali and Burkina also show considerable variation (Koch-Weser 1984, Fahr & Ebigo 2003). It seems that the exceptional geographic variability of *H. jonesi* is not simply clinal as proposed by Hayman (1964), but more likely to be linked to environmental factors such as seasonality and/or precipitation, with bats from more seasonal and/or drier regions (e.g. W Guinea, Mali, C Nigeria) smaller on average than those from less seasonal and/or wetter regions (e.g. SE Guinea, coastal Sierra Leone, Ghana). Available data indicate that specimens from Ghana attain the largest dimensions (Hayman 1964), e.g. FA: 52.4 (50–55) mm, n = 54; CrnC: 20.0 (19.0–20.6) mm, n = 15; C–M³: 6.7 (6.4–6.9) mm, n = 15.

Similar Species Only two other African *Hipposideros* have a noseleaf with the internarial septum enlarged (Table 15, p. 370):

Hipposideros curtus. Margin of posterior component low-arched in outline; internarial septum smaller, longer than broad; two weakly developed lateral leaflets on each side; frontal sac usually present (but sometimes lacking in ♀♀). Ears usually shorter (15–22 mm), less than 50% of FA.

H. marisae. Smaller (FA: 38–42 mm; CrnC: 15.4–15.8 mm). Ears shorter (15–17 mm), less than 50% of FA; no antitragal fold. Posterior component of noseleaf not elongated, low-arched in outline; internarial septum much less enlarged, oval disc longer than broad; one (rarely two) rudimentary lateral leaflet on each side; frontal sac present.

Distribution Endemic to Africa. Known only in West Africa, from 26 scattered localities in the Rainforest and Afromontane–Afroalpine BZs, the Northern Rainforest–Savanna Mosaic and the Guinea Savanna, Sudan Savanna and Sahel Savanna BZs. Recorded from Guinea, Sierra Leone, Liberia, Côte d'Ivoire, Mali, Burkina, Ghana and Nigeria (Hayman 1947, 1964, Eisentraut & Knorr 1957, Koch-Weser 1984, Happold 1987, Koopman *et al.* 1995, Fahr & Ebigo 2003).

Habitat Apparently strictly dependent on caves or artificial substitutes such as mines and, within the biotic zones exploited, the patchy distribution of this species seems determined by the availability of these roosts without apparent preference for any particular type of vegetation. Has been recorded from lowland rainforest, montane forest, dry forests in the Rainforest–Savanna Mosaic, and in savannas of the Sudan Savanna BZ and the southern part of the Sahel Savanna BZ up to 15°00'N (Douentza, Mali). A lack of records from the wettest parts of the rainforest in Sierra Leone, Liberia, Côte d'Ivoire

Hipposideros jonesi

and Ghana suggests that this habitat is avoided. Specimens have been caught over waterholes and creeks, in groves of oil-palms, tree-shrub savanna, farmed semi-deciduous forest and cutover rainforest. In Guinea, found at 1350 m on the Simandou Range, in montane grassland intersected by ravine forests (Fahr & Ebigo 2003).

Abundance Widespread in different vegetation zones but localized. The occurrence and abundance of this bat is probably determined by the availability of suitable day-roosts.

Adaptations Day-roosts include caves, disused mines, a bunker and cavities under rocks. Emergence from a day-roost in a bunker at 10°55'N in Burkina was observed at 19:00h in mid-Sep (Koch-Weser 1984). Reported to share its day-roosts with *Lissonycteris angolensis smithii*, *Nycteris macrotis*, *N. gambiensis*, *Rhinolophus denti knorri*, *R. fumigatus*, *R. landeri*, *R. guineensis*, *R. maclaudi*, *Hipposideros ruber* and *H. abae* (Eisentraut & Knorr 1957, Hayman 1964, Koch-Weser 1984, J. Fahr unpubl.). At dusk, observed drinking while flying along creeks in gallery forest (H. Knorr, SMNS). Six specimens from Djipologo, Burkina, were mist-netted over a waterhole (USNM).

Foraging and Food No information. The comparatively delicate skull and dentition suggests that this bat feeds on small to medium-sized moths and other soft-bodied, flying insects. The ears are relatively longer (i.e. in relation to the length of the forearm) than in any other African *Hipposideros* except *H. megalotis*, and are relatively much longer than the ears of the two other African species (*H. curtus* and *H. marisae*) that have noseleaves of similar shape. This suggests that *H. jonesi* has a special foraging strategy.

Echolocation Call-shape CF/FM. The CF-frequency (second harmonic) of one hand-held individual from Guinea was 48 kHz (N. Ebigo & J. Fahr unpubl.). This frequency is surprisingly low for a *Hipposideros* of its body size.

Social and Reproductive Behaviour Roosts in colonies. One colony, roosting in a disused mine in Ghana, was estimated to comprise 200–300 individuals; a sample of 54 contained 27 ♂♂ and 27 ♀♀ (Hayman 1964). Within the mine, the bats were hanging in large groups, with a few hanging singly that might have found temporary shelter after being disturbed. A group roosting in Burkina included three ♂♂ and one ♀ (Koch-Weser 1984). A group from Ghana included four ♂♂ and two ♀♀ (ROM).

Reproduction and Population Structure Litter-size and reproductive chronology not known. At 06° 30' N (near Nkawkaw, Ghana), one ♀ was lactating, and three ♂♂ had scrotal testes (5×3 mm), in early Aug (USNM).

Predators, Parasites and Diseases Ectoparasites include a bat-fly *Penicillidia allisoni* (Diptera: Nycteribiidae) (Theodor 1968).

Conservation IUCN Category: Near Threatened.

Dependent on caves and cave-like structures, therefore vulnerable to hunting by people, disturbance of roosts, and mining. Population trend unknown but possibly declining. Also vulnerable because of its patchy distribution and small area of occupancy.

Measurements

Hipposideros jonesi

Hipposideros lamottei LAMOTTE'S LEAF-NOSED BAT

Fr. Phyllorhine de Lamotte; Ger. Nimba Rundblattnase (Lamottes Rundblattnase)

Hipposideros lamottei Brosset, 1984 [publ. 1985]. Mammalia 48: 548. Pierré Richaud, Mt Nimba, 1450 m, Guinea.

Taxonomy Species-group: *bicolor*. Synonyms: none. An enigmatic species. Since its description in 1985, it was reported from various West African countries by Koopman (1989) and Koopman *et al.* (1995), although these authors considered the taxonomic status of *H. lamottei* as somewhat doubtful. However, most of the specimens on which these additional records were based have been re-examined and found to represent *H. caffer* (Decher & Fahr 2005b). Ethiopian specimens, reported as *H. fuliginosus* by Lagen *et al.* (1974), resemble *H. lamottei* more closely than *H. fuliginosus*. However, they differ from *H. lamottei* in overall size and wing shape (first and second phalanx of third digit much longer) and probably represent an undescribed species (see Geographic Variation). Chromosome number: not known.

Description Small microbat with noseleaf (posterior component roughly elliptical); brown, probably with orange-phase; ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum; frontal sac present in both sexes; thumb weakly developed with comparatively small claw and basal pad; anterior upper premolar within tooththrow. A poorly known species. Pelage fine and dense. Pelage, so far as known, brown. Orange-phase: not yet reported but likely to occur. Ears separated, comparatively and relatively short (25–29% of FA) and broad. Posterior component of noseleaf not divided into cells by vertical septa; upper margin straight (horizontal), terminating with an almost right-angle at each end; breadth of posterior component equal to or greater than breadth

of anterior component (cf. *H. ruber*). No club-shaped processes. Internarial septum not concealing nostrils. Two well-developed lateral leaflets on each side. Frontal sac present in both sexes. No anal sac. Wings and interfemoral membrane blackish-brown. Thumb, claw and basal pad weakly developed, claw length <2.5 mm, claw height <1.2 mm (cf. *H. fuliginosus*). Third finger with comparatively short phalanges (first phalanx 12.5–14.3 mm, 23–25% of FA; second phalanx 10.5–12.1 mm, 19–21% of FA) (cf. *H. fuliginosus*). Fifth metacarpal 80–90% of third metacarpal. Tibia comparatively long, and 41–42% of FA (cf. *H. fuliginosus*).

Skull fairly delicate; zygomatic width < mastoid width. CrnC relatively short (34–35% of FA) (cf. *H. fuliginosus*). Dentition relatively weak. Anterior upper premolar small, within tooththrow; canine and posterior premolar well separated.

Geographic Variation None. Sixteen specimens from Ethiopia (SMF, partly published by Lagen *et al.* 1974 as *H. fuliginosus*) are slightly larger on average than the six specimens of the type series from Mt Nimba, Guinea. However, they clearly differ from *H. lamottei* in the length of the third digit (*H. lamottei*, first phalanx: 13.2 [12.5–14.3], second phalanx: 11.4 [10.5–12.1]; Ethiopian specimens, first phalanx: 17.6 [16.3–18.3], second phalanx: 19.5 [18.7–20.7]), and probably represent an unnamed species (J. Fahr unpubl.).

Similar Species Four other African *Hipposideros* have the following combination of characters: ears separated; noseleaf with

two lateral leaflets on each side, no club-shaped processes and nostrils not concealed by internarial septum (Table 15, p. 370):

Hipposideros ruber. Body measurements usually smaller (FA: 51.1 [47–55] mm), but skull relatively larger (CrnC 38.2 [35–41]% of FA, $n = 322$). In West Africa, zygomatic width greater than mastoid width. Dentition stronger. Frontal sac usually present in ♂♂ only.

H. fuliginosus. Skull (western population) relatively larger (CrnC 36.3 [35–40]% of FA, $n = 83$), and also usually comparatively larger (CrnC: 19.9 [19.2–21.5] mm, C–M³: 7.4 [7.1–8.2] mm); zygomatic width greater than mastoid width; dentition much stronger. Frontal sac absent in both sexes. Ears relatively longer (30–31% of FA). Thumb, claw and basal pad much larger and more powerful; claw length >3 mm. Third finger with longer phalanges, first 14.3–18.7 mm, second 17.8–21.9 mm. Tibia relatively shorter (38–39% of FA).

H. beatus. Much smaller (FA: 43.7 [39–48] mm; CrnC: 16.8 [16.1–18.1] mm).

H. caffer. Much smaller (FA: 46.4 [42–52] mm; CrnC: 17.2 [16.1–18.3] mm).

(Note: *H. abae*, which is otherwise fairly similar externally, has three lateral leaflets on each side.)

Distribution Endemic to Africa. As yet only known from the vicinity of Mt Nimba, Guinea: Pierré Richaud (07° 41'N, 08° 22'W, 1400 m, in the Afromontane–Afroalpine BZ), and Grotte de Blandé near Ziéla (07° 43'N, 08° 2'W, 500 m, in the Rainforest BZ). Specimens on which the records from Sierra Leone, Liberia, Côte d'Ivoire, Ghana and Cameroon were based by Koopman (1989) and Koopman *et al.* (1995) represent *H. caffer* (Decher & Fahr 2005b).

Habitat The holotype and four other specimens were collected from horizontal mine-adits opening onto afroalpine grassland at

1400 m, and another specimen was taken from a natural cave in degraded rainforest at 500 m (Brosset 1984).

Abundance No data available but apparently very rare.

Remarks The type series (five adult ♂♂ and one adult ♀) was taken from two day-roosts, ca. 4 km apart, on Mt Nimba (Brosset 1984). One was a cave located at the base of Mt Nimba (500 m) in a valley in degraded forest. It was known to shelter a colony of *H. ruber* (Aellen 1963). Four specimens were captured, of which three represented *H. ruber* and one represented *H. lamottei*. The entrance area of the cave was formerly occupied by a large colony of *Rousettus aegyptiacus*, which has been eliminated as a result of human disturbance and exploitation (Lamotte & Roy 1998). The second day-roost was the horizontal tunnel, ca. 100 m long, of an iron-ore mine near Pierré Richaud (1450 m) that opened over a steep slope devoid of bushy vegetation. In this mine, there was a colony of ca. 130 *Hipposideros*. Ten individuals (5 ♂♂ and 5 ♀♀) were captured in Dec; five were retained as the type series of *H. lamottei* and the others identified with *H. lamottei* on the basis of their external characters. There were no juveniles, and none of the ♀♀ was visibly pregnant. Four *Lissonycteris angolensis smithii* also roosted in this mine. Nothing else is known about the habits of *H. lamottei*. Its comparatively small skull and weak dentition suggest that it takes softer prey than similar-sized hipposiderids such as *H. ruber* and *H. fuliginosus*.

Conservation IUCN Category: Critically Endangered.

Only known from one location (two localities ca. 4 km apart) and six individuals. Known extent of occurrence extremely small and within a region seriously affected by civil war in adjacent Liberia. Population size not known but likely to be small; population trend inferred to be declining. Major threats: large-scale mining (past and present), logging and agriculture. Probably vulnerable to disturbance and direct exploitation in its day-roosts. Surrounding areas have been surveyed recently but the species has not been found elsewhere (Fahr & Ebigo 2003, Fahr *et al.* 2006).

Hipposideros lamottei

Jakob Fahr

Hipposideros marisae AELLEN'S LEAF-NOSED BAT

Fr. Phyllorhine d'Aellen; Ger. Marisas Rundblattnase

Hipposideros marisae Aellen, 1954. Rev. Suisse Zool. 61: 474. Rocher de la Panthère Blanche, Duékoué, Côte d'Ivoire.

Taxonomy Species-group: *bicolor*. Synonyms: none. Closely related to *H. jonesi* and *H. curtus*. Chromosome number: not known.

Description Very small microbat with noseleaf (posterior component roughly elliptical); greyish-brown with orange-phase; ears separated; noseleaf with a somewhat enlarged internarial septum, which partly conceals the nostrils and one (rarely two) very small lateral leaflet on each side; frontal sac present in both sexes. Sexual dimorphism: no information. Dorsal pelage (grey-phase) greyish-brown; hairs with dark grey bases and paler tip. Ventral pelage paler; hairs with grey or brown at base and pale grey or whitish at tip. Orange-phase: dorsal pelage tawny-orange to cinnamon; ventral pelage paler. Ears comparatively small but of medium relative length (39–43% of FA); broad, subtriangular, bluntly pointed with faint concavity in outer margin just below tip; each ear with 12–13 internal folds. Antitragus with no fold. Noseleaf longer than broad (Figure 68d). Posterior component divided into four cells by three vertical septa; upper margin low-arched in outline; internarial septum moderately enlarged, pad-like, forming a comparatively small, oval disc (longer than broad), which partly conceals the nostrils; usually only one rudimentary lateral leaflet on each side, rarely two (Liberia: SMNS 38563). Frontal sac present in both sexes; opening horizontally, lined with stiff, black hairs. No anal sac. Wings and interfemoral membrane dark grey. Fifth metacarpal 100–105% of third metacarpal. Tail 36–44% of HB.

Skull delicate with short, slender, pointed rostrum and relatively high braincase; zygomatic width usually < mastoid width (*contra* Aellen 1954). Sagittal crest weakly developed. Cochleae moderately enlarged, their breadth ca. 2.5 times their distance apart. Upper incisor unicuspid. Anterior upper premolar very small, slightly displaced labially; canine and posterior upper premolar almost in contact. Anterior lower premolar ca. half height of posterior lower premolar or slightly higher.

Geographic Variation None.

Similar Species Only two other African *Hipposideros* have a noseleaf with the internarial septum enlarged (Table 15, p. 370):

Hipposideros curtus. Usually larger (FA: 43.5 [42–47] mm; CrnC: 17.0 [16.3–17.5] mm). Ear: 15–22 mm. Antitragal fold small. Internarial septum more enlarged, oval disc larger; two weakly developed lateral leaflets on each side. Frontal sac sometimes absent in ♀♀.

H. jonesi. Larger (FA: 44–50 mm; CrnC: 17.6–19.1 mm). Ear longer (21–28 mm, 45–60% of FA). Antitragal fold distinct. Posterior component of noseleaf elongated, subtriangular in outline; internarial septum much more enlarged, disc broader than long; one long well-developed lateral leaflet on each side. No frontal sac.

Hipposideros beatus and *H. caffer* are somewhat similar, but do not have an enlarged internarial septum that partly conceals the nostrils.

Hipposideros marisae

Distribution Endemic to Africa. Apparently restricted to a very small region in the Rainforest BZ (Western Region). Known from only seven localities in the highlands of SE Guinea, N Liberia and W Côte d'Ivoire (Aellen 1954, 1963, Kuhn 1965, Roche 1971, Hill 1982a, Koopman *et al.* 1995, J. Fahr unpubl.), covering ca. 23,800 km² in an area to the north-west and south-east of Mt Nimba.

Habitat Most records are from drier and wetter types of lowland and sub-montane rainforest, up to 650 m. The type locality in Côte d'Ivoire was in a semi-deciduous forest (now destroyed). Most of the known individuals were found in caves (Aellen 1954, 1963, Wolton *et al.* 1982), suggesting that caves might be an essential component of the habitat of this species.

Abundance Uncertain; apparently extremely localized and rare. Since the description of this bat in 1954, only 15 specimens have been collected.

Remarks The holotype, a ♂, was roosting in a fissure of a cave. It shared the cave with a small colony of *H. ruber* (Aellen 1954, as *H. caffer guineensis*). A single adult ♀ was taken from a system of very small caves in a rocky outcrop; this roost was also shared with *H. ruber* (Wolton *et al.* 1982). One individual was caught when it flew into a room of a house in Guinea (Roche 1971). In late Oct, a group including four ♂♂ and five ♀♀ was caught in a cave situated near the bed of a torrential forest creek (Aellen 1963, MHNG, MNHN). Probably feeds on small, soft-bodied flying insects as it is one of the smallest African hipposiderids.

Conservation IUCN Category: Vulnerable.

Distribution very small; only seven localities known. Population size not known; trend inferred to be declining. Major threats: large-scale loss and degradation of habitat (caused by logging, agriculture and mining [past and future]), and disturbance and/or exploitation by humans in caves used as day-roosts. Occurs in region of high human population density that has been seriously affected by the recent civil conflict in Liberia and adjacent regions.

Hipposideros megalotis LARGE-EARED LEAF-NOSED BAT

Fr. Phyllorhine à grandes oreilles; Ger. Großohr-Rundblattnase

Hipposideros megalotis (Heuglin, 1862). Nova Acta Acad. Caes. Leop.-Carol., Halle 29 (8): 4, 8. Keren, Bogos Land, Eritrea.

Taxonomy Originally *Phyllorhina megalotis*. Synonyms: none. Sometimes placed in subgenus *Syndesmotis* Peters 1871 (e.g. Gaucher & Brosset 1990). Senna (1905) raised *Syndesmotis* to generic rank. This is rejected by Hill (1963), Koopman (1993) and Simmons (2005), but Legendre (1982) proposes its revalidation as a genus containing *megalotis* together with *vetis*, a fossil form. *Hipposideros megalotis* is considered to be the only extant member of the *megalotis* species-group, and it is considered the most primitive species in the genus *Hipposideros* (Hill 1963, Legendre 1982). The fossil record shows that hipposiderids belonging to the subgenus *Syndesmotis* were present in S France and Morocco during the early and middle Miocene (Legendre 1982). Chromosome number: not known.

Description Very small microbat with noseleaf (posterior component roughly elliptical); smallest African *Hipposideros*; sepia brown or bright cinnamon; ears large, rounded, joined by low frontal band; noseleaf with no lateral leaflets. Sexes similar in colour. Pelage fluffy; mid-dorsal hairs 8–9 mm. Dorsal pelage (grey-phase) sepia brown to dark rusty-brown; hairs beige to almost white with terminal quarter sepia-brown or dark rusty-brown. Ventral pelage (museum specimens) cream to yellowish-beige (perhaps white in living bats) becoming pale sepia-brown on chin and near flight-membranes. Orange-phase: dorsal pelage bright cinnamon with silky sheen; hairs pale cinnamon with terminal quarter cinnamon; ventral pelage pale cinnamon with bright cinnamon on chin. Ear length comparatively short to medium, but relatively long (51–68% of FA), broad, joined at base by a low, inconspicuous frontal band; inner and outer margins convex, tip rounded. Noseleaf small and simple. Posterior component divided into four cells by three weakly defined septa; upper margin sinuous and notched. No lateral leaflets. Frontal sac absent, but there are paired glandular bodies behind the noseleaf. Wings and interfemoral membrane brown in both phases. Tibia 40–42% of FA. Tail 40–42% of HB.

Skull small and elongated with narrow rostrum and inflated braincase; zygomatic arches moderate; zygomatic width < mastoid

width. Sagittal crest low. Cochleae moderately enlarged, their breadth ca. three times their distance apart. Upper incisor slightly bicuspid. Upper canine relatively short (41 [35–45]% of C–M³, n = 12). Anterior upper premolar absent; canine and posterior upper premolar either in contact, almost in contact or well separated. Anterior lower premolar ca. three-quarters the length and half the height of the posterior lower premolar.

Geographic Variation None recorded.

Similar Species None (Table 15, p. 370).

Hipposideros megalotis

Distribution In Africa, recorded from the Afromontane–Afroalpine and Somalia–Masai Bushland BZs in Eritrea, Ethiopia, Djibouti and Kenya (Largen *et al.* 1974, Legendre 1982, Aggundey & Schlitter 1984). According to Koopman (1993) and Nowak (1999), *H. megalotis* also occurs in Somalia, but their information originates from an erroneous indication by Gaucher & Brosset (1990). Extraliminally: one record from Jeddah in Saudi Arabia (Gaucher & Brosset 1990).

Habitat Mostly recorded from highlands and uplands in Ethiopia and Kenya. Localities are in undifferentiated afromontane vegetation, mosaic of East Africa evergreen bushland and secondary *Acacia* wooded grassland, Somalia–Masai semi-desert grassland and shrubland, Somalia–Masai *Acacia–Commiphora* deciduous bushland and thicket, and evergreen and semi-evergreen bushland and thicket (terminology: White 1983). Considered to be a relict species by Kingdon (1974).

Abundance Uncertain. Appears to be a rare species (Gaucher & Brosset 1990).

Remarks During the day, has been found in a farmhouse at Nakuru, Kenya (Hayman 1954) and in a lava tube ca. 200 m long, 2–3 m high with some lower portions, on Mt Suswa, Kenya (Kock & Hillman 1975). The entrance to the lava tube was a hole ca. 1 m in diameter at the base of a fig tree *Ficus* sp. The bats were roosting at the far end in a region ca. 2 m high; temperature 28–30 °C; humidity high. The bats, fewer than 100 and all adults, were hanging freely from the ceiling of the cave, in loose groups. A ♀ with one embryo of unrecorded size was taken near Nakuru in the short wet season (Dec).

Conservation IUCN Category: Least Concern.

Population trend: not known. Although seldom recorded, it exploits a range of habitats and its numbers are unlikely to be declining fast enough for qualifying as Near Threatened. The major threats are loss and degradation of habitat because of human activities (smallholder farming, agro-industry farming, tourism and other disturbances).

Hipposideros ruber NOACK'S LEAF-NOSED BAT

Fr. Phyllorhina rousse; Ger. Noacks Rundblattnase

Hipposideros ruber (Noack, 1893). Zool. Jahrb. Abt. Syst. Oekol. Geogr. Tiere 7: 586. Ngerengere River, Eastern Province, Tanzania.

Taxonomy Originally *Phyllorhina ruber*. Species-group: *bicolor*. Synonyms: *centralis*, *guineensis*, *naipu*. Subspecies: two. Closely related to *H. caffer*. Although *H. caffer* and *H. ruber* are distinctly different in most parts of their geographic ranges, they are not easily distinguished in Angola, which led Crawford-Cabral (1986) to question the specific status of *H. ruber*. Recently, Vallo *et al.* (2008) reported three genetic forms of *H. ruber* at least one of which probably represents a distinct species: all three may correspond to named taxa but their proper taxonomic assignment was not assessed in this publication. Chromosome number: not known.

Description Small microbat with noseleaf (posterior component roughly elliptical); greyish-brown with orange-phase; ears separated; noseleaf with two lateral leaflets on each side, no club-like processes and nostrils not concealed by internarial septum; frontal sac present in ♂♂; thumb weakly developed with comparatively small claw and basal pad. Sexes similar in colour; in Congo, ♀♀ on average a little larger than ♂♂ (Allen & Brosset 1968, as *H. caffer*). Pelage fluffy, fine, silky; mid-dorsal hairs ca. 9 mm. Dorsal pelage medium to dark greyish-brown, sometimes suffused with cinnamon; hairs fawn with brown at base and grey-brown at tip. Ventral pelage same

as dorsal pelage or paler. Orange-phase: dorsal pelage bright rusty-brown with golden sheen to pale gold (hairs unicoloured); ventral pelage similar. Bats moult into greyish-brown phase; pelage changes to orange-phase as oxidized by fumes within day-roost (Wolton *et al.* 1982). Ears comparatively short, but relatively short to medium (28–41% of FA); broad, inner margin convex, outer margin convex becoming concave near tip; tip pointed. Antitragus shallow, often with slight to distinct point resulting from thickening at the antitragal fold. Noseleaf approximately as in Figure 68f. Posterior component with transverse serrated supplementary structure behind the upper margin; not elongated, not divided into cells by well-defined vertical septa, upper margin with low-arched outline. No club-shaped processes. Internarial septum weakly developed, not concealing nostrils. Two lateral leaflets on each side. Frontal sac well developed in ♂♂ only, opening horizontally: ♀♀ with line of longer, darker hairs arising from a shallow horizontal groove. No anal sac. Wings and interfemoral membrane blackish-brown in both phases. Thumb, including claw and basal pad, weakly developed (cf. *H. fuliginosus*) (claw length 2.3 [1.8–2.7] mm, claw height 1.1 [0.9–1.4] mm). Fifth metacarpal 87–94% of third metacarpal. Tibia 35–48% of FA. Tail 24–38% of HB.

Skull short, broad; zygomatic width $>$ or $<$ mastoid width. In West Africa, zygomatic width $>$ mastoid width (cf. *H. lamottei*). Skull relatively large (CrnC: 38.2 [35–41]% of FA, $n = 322$; J. Fahr pers. comm.) (cf. *H. lamottei*). Median posterior nasal component of rostral swelling relatively wide with narrow lateral inflations (Figure 72c) (cf. *H. caffer*). Sagittal crest low. Cochleae not enlarged, their breadth equal to their distance apart or a little greater. Upper incisor weakly bicuspid, outer cusp very weakly developed. Upper canine of medium relative length (48 [43–50]% of C–M³, $n = 50$). Anterior upper premolar small or minute, slightly displaced labially; canine and posterior premolar not in contact (usually well separated). Anterior lower premolar one half the length and height of posterior premolar or more.

Geographic Variation Two subspecies are recognized by Koopman (1994); see also Taxonomy:

H. r. ruber (= *centralis*, *niapu*): Central African Republic and Angola to eastern Africa from Ethiopia to Malawi.

H. r. guineensis: Senegal to Gabon and Bioko I.

Similar Species Four other African *Hipposideros* have the following combination of characters: ears separated; noseleaf with two lateral leaflets on each side, no club-shaped processes, nostrils not concealed by internarial septum (Table 15, p. 370):

Hipposideros caffer. Usually smaller, especially where sympatric (FA: 46.8 [42–52] mm; CrnC: 17.2 [16.1–18.3] mm). Median posterior narial compartment of the rostral swelling relatively narrow with wide lateral inflations. Dorsal pelage (grey-phase) more grey than brown. Typically found in savanna woodlands and bushveld, less common in forests.

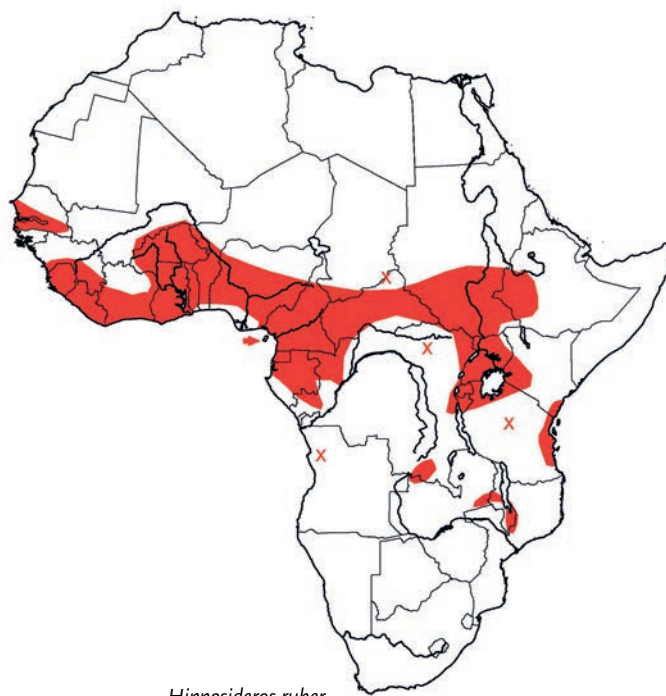

H. beatus. FA shorter (43.7 [39–48] mm). Tibia usually shorter (16.1 [15–19] mm). Anterior upper premolar greatly reduced and fully displaced labially; canine and posterior premolar in contact or almost so.

H. fuliginosus. Larger on average in all measurements (FA [western population]: 55.0 [51–60] mm, FA [eastern population]: 62.6 [60–64] mm; CrnC [western population]: 19.9 [19.2–21.5] mm, CrnC [eastern population]: 23.2 [22.8–23.4] mm). Thumb, claw and basal pad larger; claw length > 3 mm. Frontal sac absent in both sexes but sometimes there is a patch of bare skin. Echolocation CF-frequency (western population) lower (120–121 kHz).

H. lamottei. Body measurements usually larger (FA: 55.8 [55–57] mm) but skull relatively smaller (CrnC: 34–35% of FA). Zygomatic width $<$ mastoid width. Dentition weaker. Frontal sac present in both sexes.

(Note: *H. abae*, which is otherwise fairly similar externally, has three lateral leaflets on each side.)

Distribution Endemic to Africa, Príncipe and São Tomé. Widely distributed, mainly in the Sudan Savanna and Guinea Savanna BZs, Northern and Eastern Rainforest–Savanna Mosaics, Rainforest BZ, Afromontane–Afroalpine BZ of the Ethiopian Highlands, and Zambezian Woodland BZ. Extends marginally into the Sahel Savanna and Somalia–Masai Bushland BZs. Rarely reported from

Hipposideros ruber

eastern half of the Congolian rainforest. In Africa, recorded from Gambia and Senegal to Ethiopia and south to Angola, Malawi and Mozambique; also Bioko I. Not known south of Zambezi R. (Hutton 1986). Records from Zimbabwe in Fenton & Bell (1981), Bell & Fenton (1984) and Fenton (1985) refer to *H. caffer*. If material from Central African Republic and Angola to eastern Africa (from Ethiopia to Malawi) represents only one subspecies (Koopman 1994), gaps in the distribution south of the Equator perhaps reflect insufficient collecting. Mapped from country checklists (see order Chiroptera), other literature and museum records.

Habitat Typically found in lowland rainforest, and in or near wetter areas (including riverine, relict and montane forests) in woodland savanna zones. Probably typically a forest species (cf. *H. caffer*), but this needs further investigation.

Abundance Uncertain. Fairly common in collections; probably fairly common in suitable habitats.

Adaptations Aspect ratio low; wing-loading very low. Flies slowly with bursts of speed and with agility and considerable manoeuvrability. Frequently glides for short distances. Can take off from ground and hover briefly. Turns by banking (minimum radius < 25 cm) and by stalling-and-twisting. By day, has been found hanging, freely, in caves, crevices, mine-adits, enclosed roofs, abandoned buildings, under a bridge, in hollow trees and burrows of large mammals (Lang & Chapin 1917b, Verschuren 1957, Poché 1975, Schlitter *et al.* 1982, Wolton *et al.* 1982, Kityo & Kerbis 1996, Grubb *et al.* 1998). Humidity in day-roosts is very variable (Verschuren 1957). In Sierra Leone, sometimes roosts with *Rhinolophus guineensis*, *H. abae* and *H. jonesi* (Grubb *et al.* 1998), and in Cameroon, reported roosting with *H. fuliginosus* (Aellen 1952). Captive individuals in Malawi did not become torpid during day when ambient temperature was 21–24 °C. Captive bats offered water twice daily invariably drank every time, and the predicted mean

maximum urine concentration is comparatively low (3133 mOsmol/kg) (Happold & Happold 1988). Predicted to need to drink several times/night in the wild.

Foraging and Food Forages in cluttered environments and avoids open habitats (Jones *et al.* 1993). Foraging predicted to include slow-hawking and gleaning as in *H. caffer*. In Liberia, *H. ruber* emerged and began foraging just as it was getting dark; returned to day-roost with full stomachs after two hours; foraged again intermittently through night with peak just before dawn (Wolton *et al.* 1982). Diet, in West Africa in wet season, ca. 84% beetles with some moths, Diptera and Isoptera (Jones *et al.* 1993). Beetles were also found in stomachs of five bats from Garamba N. P., DR Congo (Verschuren 1957).

Echolocation Call-shape CF/FM. CF-frequency shows only a little variability in different localities:

Gambia: 134.13 ± 1.84 kHz (8 ♂♂); 131.85 ± 0.99 kHz (20 ♀♀); Jones *et al.* 1993).

Côte d'Ivoire: 132–144 kHz (J. Fahr & N. Ebigbo pers. comm.).

E DR Congo (Irangi): 136.2 (131.8–138.2) kHz (5 ♂♂), 132.8, 135.1 kHz (2 ♀♀; Heller 1992).

Malawi: 133–135 kHz (1 ♂, 30 calls), 140 kHz (1 ♀, 30 calls; M. Happold unpubl.) (Figure 64a).

(Note: mean \pm 1 S.D. in some cases.)

The possibility that there are inconsistent sex-related differences in CF-frequency calls for investigation.

Social and Reproductive Behaviour Very little known. Typically roosts in small to very large (several hundreds) groups; occasionally both ♂♂ and ♀♀ roost singly. Individuals hang apart but in close proximity to group-members. In Liberia, ♂♂ roost apart from ♀♀ at least during Jul–Sep (no data for Mar when births occur), suggesting formation of maternity colonies. In Garamba N. P., groups ranging in size from 5 to 71 were comprised of both ♂♂ and ♀♀; usually ♀♀ outnumbered ♂♂ by 2–3 to 1 (Verschuren 1957).

Reproduction and Population Structure Litter-size: one. Reproductive chronology is restricted seasonal monoestry; retarded embryonic development recorded at one locality. At 7°S in Tanzania, copulation, ovulation, fertilization in Jun–Jul, retarded development for ca. two months, parturition in Dec, lactation Dec–Feb (Howell

1976 in Bernard & Cumming 1997). At 07° 39' N (Mt Nimba, Liberia), births occur in Mar (Wolton *et al.* 1982). At 04° 40' N (Garamba N. P., NE DR Congo), births occur in late Mar to early Apr (Verschuren 1957). At 2–3° N in Equatorial Guinea, three ♀♀ with large embryos in Oct, lactating ♀♀ in Nov (Jones 1971, as *H. caffer*) and, at 9° N in Central African Republic, all of seven ♀♀ were lactating in late May (Schlitter *et al.* 1982). In Gabon, Brosset (1968) reported that within one population, some colonies had a boreal cycle with births in Mar, while others had an austral cycles with births in Oct: however it is not known if Brosset studied *H. ruber*, *H. caffer* or both.

Predators, Parasites and Diseases The remains of one individual were found in the scats of a mongoose *Herpestes naso* (Hutterer & Ray 1997). Ectoparasites include bat-flies *Penicillidia allisoni*, *P. fulvida*, *P. senegalensis* (Diptera: Nycteribiidae), *Brachytarsina longiarista* and *Raymondia seminuda* (Diptera: Streblidae) (Aellen 1952, Wolton *et al.* 1982).

Conservation IUCN Category: Least Concern.

Widely distributed, but population trend not known, and likely to be threatened by loss and degradation of forest habitat as result of wood extraction and shifting agriculture.

Hipposideros vittatus STRIPED LEAF-NOSED BAT

Fr. Phyllorhine rayée; Ger. Gestreifte Rundblattnase

Hipposideros vittatus (Peters, 1852). Naturwiss. Reise Mossambique, Säugeth., p. 32. Ibo I., Cap Delgado group, Mozambique.

Taxonomy Originally *Phyllorhina vittata*. Species-group: *commersoni*. Synonyms: *marungensis*, *mostellum* and perhaps *viegasi*. The status of *viegasi* is uncertain (Simmons 2005) but is tentatively retained here in *H. gigas* following Hayman & Hill (1971). Subspecies: none currently recognized. The taxonomy of the *H. commersoni* group is problematical and in need of revision (see Genus *Hipposideros*). Hill (1963) considered *vittata* (Peters, 1852) to be a synonym of *H. commersoni gigas*.

Subsequently, although *vittata* was considered more likely to be a synonym of *marungensis* (Noack, 1887), most authors continued to refer to these forms by the better-known junior synonym, *H. c. marungensis* (e.g. Hayman & Hill 1971), possibly because they considered that the affinity of *vittata* was still uncertain. As *vittata* is currently considered synonymous with *marungensis*, the seniority of *vittata* is provisionally recognized here. As *H. c. marungensis*, *H. vittatus*

was formerly considered to be a subspecies of *H. commersoni* (e.g. Hill 1963, Koopman 1993) but differences in morphology and echolocation calls indicate that *H. vittatus*, and also *H. gigas*, are distinct species (Pye 1972, McWilliam 1982). *Hipposideros commersoni* is now considered restricted to Madagascar (Simmons 2005) and, in some parts of Africa, *H. vittatus* is now known to occur sympatrically with *H. gigas*. Consequently, the distributions of both *H. vittatus* and *H. gigas* are expected to be considerably more extensive than pre-2005 records indicate and, furthermore, it will be some time before pre-2005 information attributed to *H. commersoni* in Africa, *H. c. marungensis* and *H. c. gigas* is reallocated to its correct species. Chromosome number (South Africa): $2n = 52$ (Rautenbach *et al.* 1993).

Description Very large microbat with noseleaf (posterior component roughly elliptical); robustly built; pale to medium brown with silver, white and brown markings; second largest African hipposiderid; ears separated; noseleaf with three lateral leaflets on each side, no club-shaped processes and nostrils not concealed by an enlarged internarial septum; not easily distinguished morphometrically from *H. gigas*. Males on average larger than ♀♀. Pelage soft, not woolly, sparse on hindquarters; mid-dorsal hairs 5–8 mm. Dorsal pelage (grey-phase) medium to pale brown (fawn) or reddish-brown; paler and with silvery frosting on head, nape, rump and next to wings; hairs unicoloured or with darker base; some with silvery-grey at tip. Ventral pelage medium to pale brown, with silvery frosting; flanks white; armpits white or yellow, partly surrounded by C-shaped brown stripe that curves around the shoulder. In Zimbabwe, parous ♀♀ are rich reddish-brown whereas ♂♂ are greyish (Cotterill & Fergusson 1999). Orange-phase: no information. Ears comparatively medium to long but relatively short (26–33% of FA); brown; triangular, tapering to bluntly pointed tip with little or no concavity in outer margin below tip. Antitragus shallow. Noseleaf similar to that of *H. gigas* (Figure 68e). Posterior component divided into four shallow cells by three weak vertical septa. Three lateral leaflets on each side. Frontal sac present in both sexes but more prominent in reproductively active ♂♂; opening vertically. No anal sac. Wings and interfemoral membrane brown. Fifth metacarpal 92–99% of third metacarpal. Tibia 39.2 (32–45)% of FA, $n = 19$. Tail 31.0 (21–46)% of HB.

Skull large with broad rostrum; zygomatic arches massive; zygomatic width > mastoid width. Sagittal crest greatly developed (especially in ♂♂) and merging with the supraorbital ridges. Infraorbital foramen large, elongate and closed by narrow bar. Cochleae not enlarged, their breadth only a little greater than their distance apart (cf. *H. camerunensis*, *H. cyclops*). Upper incisor slightly bicuspid. Upper canine relatively long (54 [48–60]% of C–M³, $n = 10$). Anterior upper premolar very small, displaced labially; canine and posterior premolar in contact or nearly so. Anterior lower premolar half the length and height of posterior premolar or slightly less.

Geographic Variation Uncertain. No subspecies recognized by Simmons (2005).

Similar Species Only one other African *Hipposideros* has FA >79 mm and no club-shaped processes on noseleaf (Table 15, p. 370):

Hipposideros gigas. Larger on average (FA [♂♂]: 107.9 [100–124] mm, FA [♀♀]: 103.8 [95–116] mm). Pelage longer and

slightly woolly. Echolocation CF-frequency ca. 56 kHz (at least in Kenya). Predominantly a forest species. In at least some areas of sympatry, FA measurements of adults of same sex do not overlap – e.g. in coastal Kenya, *H. gigas*: FA ♂♂: 109–122 mm; FA ♀♀: 105–116 mm (cf. *H. vittatus*: FA ♂♂: 90–108 mm; FA ♀♀: 85–98 mm) (A. N. McWilliam pers. comm.).

Distribution Endemic to Africa. Recorded with reasonable certainty from the Zambezian Woodland and Coastal Forest Mosaic BZs, with marginal extensions into the Somalia–Masai Bushland BZ and the Kalahari Desert. Probably also exploits Sudan Savanna and Guinea Savanna BZs (e.g. in Central African Republic and Nigeria). Traditionally thought to occur only on the eastern side of Africa, from Ethiopia and Somalia to South Africa, but now considered to occur also in Angola and Namibia, and considered likely to occur much further afield, including Central African Republic and Nigeria (see Taxonomy). Mapped from localities of museum and published specimens whose identification (if not already assigned to *vittatus* or *marungensis*) could be verified by FA and GLS measurements. Specimens from three localities in Nigeria are tentatively considered to represent *H. vittatus* because all three specimens are ♂♂ of FA: 98–102 mm and because the habitat is not typical of *H. gigas* (see Bergmans 1977b). A specimen from Central African Republic, recorded as *H. commersoni gigas* (Schlitter *et al.* 1982), is a ♀ with FA: 94 mm and, based on FA and habitat, this specimen is also more likely to represent *H. vittatus*. Possibly, the specimens from Burkina (Koopman *et al.* 1978) and N Togo (De Vree *et al.* 1969) (mapped as *H. gigas*) also represent *H. vittatus*, but no measurements are available for these specimens. Since this profile was submitted, *H. vittatus* was shown to occur in Sierra Leone by Decher *et al.* (2010): not mapped.

Habitat Recorded mostly from woodland savannas and coastal forests. Extends into drier bushlands and (rarely) into Sahel savanna, but possibly only during wet seasons and/or near riverine woodlands

Hipposideros vittatus

and forests. Apparently absent from most of the Congolian rainforest, and not yet recorded from montane or arid habitats.

Abundance Uncertain; very common in some localities.

Adaptations Aspect ratio low; wing-loading high for an African microbat, very high for an African hipposiderid; flight-speed variable; manoeuvrability moderate. Can take off from ground. Turns by banking (minimum radius of turn just under 50 cm) and by stalling-and-twisting; despite its size, sustained flight in a 1×1×1 m enclosure for up to two circuits/flight (5 bats, 10 flights each; M. Happold unpubl.). By day, usually hangs, free or in contact, in caves, but has also been found roosting singly in foliage in inland Kenya (Vaughan 1977), in the roof of a traditional hut (R. C. Wood in Kershaw 1922) and under eaves of buildings (Taylor 2000). Fidelity to roosts in foliage was noted by Vaughan (1977). In Malawi (at 20–21 °C) and in Mabura Cave in Zimbabwe, *H. vittatus* does not become torpid during the day (Happold & Happold 1988, Cotterill & Fergusson 1999). Not known to hibernate. Heavy fat deposits have been recorded when insects are maximally abundant (Cotterill & Fergusson 1999). This species was present at Masalani (near Kibwezi, inland Kenya) only during the two annual wet seasons when insects are abundant, and Vaughan (1977) assumed they moved to and from the coastal forests, perhaps using riverine habitats as their route. Migration away from coastal Kenya in Oct and again in Mar, to take advantage of wet seasons that arrive earlier and more predictably inland than at the coast, was confirmed by McWilliam (1982).

Foraging and Food Near Masalani, *H. vittatus* foraged, mainly for large flying beetles, by fly-catching (Vaughan 1977). Individuals left their daytime roosts (in foliage of trees) ca. 30 minutes after sunset, and flew directly to habitually used perches 40–75 m away. They flew within 2 m of the ground, possibly to avoid Bat Hawks *Macheiramphus alcinus*. Perches were typically 6–7 m above ground (range 4–15 m), in riverine trees; each night, one individual used at least five perches along a 45 m line. Perches typically commanded views of unobstructed spaces beneath the tree's canopy. Perching bats scanned a 180 degree arc, and flew to intercept prey that came within a 10 m radius; this presumably being the maximum distance at which prey can be detected by their echolocation. The bats swooped down towards the prey, then carried it (apparently laboriously) to the perch where, for the next 3–8 min, it was chewed and eaten. An hour of intense foraging, with 1–2 flights/min, was followed by an hour or more with only ca. three flights per hour. Occasionally, the bats made seemingly reconnaissance flights around the tree containing the perch, and perhaps gleaned prey from the flowers or foliage. This behaviour tended to occur later in the night when fewer beetles were flying. Even during periods of intense fly-catching, the bats spent 4–5 times longer at the perch than in flight and it is assumed that, for these large, heavy bats, fly-catching and the selection of large prey optimizes energy return per unit of foraging time. Feeds mainly on large beetles (Vaughan 1977, Fenton 1985), but undoubtedly gorges seasonally on winged termites, and R. C. Wood (in Kershaw 1922) observed hundreds of *H. vittatus* feeding on large larvae of weevils found in wild figs in Malawi.

Echolocation Call-shape CF/FM. Pye (1972) observed a bimodal distribution of CF-frequencies in a colony of '*H. commersoni*' inhabiting caves in Kenya: the CF-frequencies were ca. 56 kHz and

ca. 66 kHz with a silent interval of 8 kHz. It is now known that *H. gigas* emits the 56 kHz calls, and that *H. vittatus* emits the ca. 66 kHz calls. CF-frequency (Malawi): 61–63 kHz (n = 4 bats identified by FA; Figure 64b; M. Happold unpubl.). CF-frequency in Zimbabwe (n = 3 bats) and in South Africa (n = 2 bats) is 62 kHz (Fenton & Bell 1981, Aldridge & Rautenbach 1987); bats identified with *H. vittatus* on basis of habitat.

Social and Reproductive Behaviour Apparently forages singly (Vaughan 1977, Smithers 1983), but typically roosts in groups (colonies) of 50–400 individuals, although colonies of more than 100,000 are known (Cotterill & Fergusson 1999). Occasionally roosts singly, usually in day-roosts other than caves (species not confirmed). A 15-month study at Mabura Cave, Zimbabwe, provided evidence that the mating system is a form of resource-defence polygyny (*sensu* Vehrencamp & Bradbury 1984) (Cotterill & Fergusson 1999). From Feb to Jun, breeding ♂♂ defended roost-site territories (marked by patches of urine ca. 30 cm apart) on the exposed walls and ceilings. During this time, subadult ♂♂ clustered into rock crevices within the cave, often alongside parous and subadult ♀♀. Copulation occurred in Jun–Jul, when a ♀ landed near a ♂ on his territory. Copulations are prolonged (ca. 30 minutes), ejaculates are large and copulatory plugs are formed in the vaginae, suggesting the occurrence of sperm competition. Territoriality ceased after the mating-season and, in Aug–Mar, the adult ♂♂ clustered together in crevices. After the mating-season, pregnant ♀♀ roosted elsewhere until late-Oct when they returned to Mabura Cave to give birth and lactate. They established maternity-roosts in extensive side chambers, which had high temperatures and humidities and high levels of CO₂ and ammonia. When flying within the cave, mothers carried their neonates, but did not carry them while foraging; when carried, neonates fasten their teeth around a pubic nipple and cling to the mother's fur with their hindfeet. Adult ♀♀ were again absent from Mabura Cave in Mar–Apr, and it seems likely that they migrate at this time, and also during mid-pregnancy, to remote areas that have rainfall and abundant insects during these months.

Reproduction and Population Structure Litter-size: one. The reproductive chronology appears to be restricted seasonal monoestry at both low and high latitudes. At 04°03'S in coastal Kenya, copulation occurs in the long dry season (Jul–Aug), and births during the long wet season (Mar–Apr) (McWilliam 1982). At 18°S in C Zimbabwe, copulation occurs in the cool dry season (mid-Jun to mid-Jul), parturition at beginning of wet season (late Oct to early Nov), and lactation continues for at least 13 weeks until mid-Mar (Cotterill & Fergusson 1999). Juveniles can make short gliding flights within the roost when ca. two weeks old but remain dependent on mothers' milk for at least 13 weeks. FA length almost doubles within first 34 days.

Predators, Parasites and Diseases Anciaux de Faveaux (1984) lists parasites of '*H. commersoni*' in Africa, but it is not certain which have been recorded from *H. vittatus* and which from *H. gigas*.

Conservation IUCN Category: Near Threatened.

Almost meets criteria for qualifying as threatened. Populations are severely fragmented. Major threats: loss of habitat and disturbance

of colonies in caves (by hunters, miners and recreational cavers). Mining of guano from caves threatens populations in Zimbabwe, especially where mining is permitted during the mating, parturition and lactation seasons (Cotterill & Fergusson 1999).

GENUS *Triaenops*

Trident Bats

Triaenops Dobson, 1871. J. Asiat. Soc. Bengal 40: 455. Type species: *Triaenops persicus* Dobson, 1871.

Triaenops is a polytypic genus that was previously considered to have four species, *T. persicus* (with *afer* and *majusculus* as subspecies) distributed from Pakistan, Iran and southern Arabia to Africa, and three other species confined to Madagascar and nearby islands (Simmons 2005). Recently, however, the genus has been revised (based on morphological and molecular evidence) by Benda & Vallo (2009), who split *T. persicus* into three species: *T. afer*, which is monotypic and endemic to Africa, and *T. persicus*, and a new species

(*T. parvus*), which occur in the Middle East. These authors have proposed a new genus, *Paratriaenops*, for four other species that were previously placed in *Triaenops*: three (*P. menemena*, *P. furculus* and *P. auritus*) that are endemic to Madagascar and a fourth (*P. pauliani*) that is endemic to the western Seychelles.

Triaenops is distinguished from other genera of hipposiderids in Africa by the following combination of characters: posterior component of noseleaf trident-shaped (i.e. with three tall, spear-

Figure 75. *Triaenops afer*. Flight membranes and bones of wing, hindlimb and tail. Skull (BMNH 79.11.12.1).

like projections arising from the upper edge) (Figure 65d), tail fully enclosed by interfemoral membrane (Figure 75) and FA: 49–60 mm (in Africa). Furthermore, the posterior component is divided into deep cells giving it a pitted appearance (cf. *Asellia*) (Figure 65). The skull (Figure 75) has each zygomatic arch expanded into a broad plate; braincase scarcely higher than rostrum; rostrum with

prominent nasal swellings; premaxillae unusually thick; upper canine with strong posterior secondary cusp. Dental formula $^{1123}/_{2123} = 30$.

The species occurring in Africa is *Triadenops afer*.

Meredith Happold

Triadenops afer AFRICAN TRIDENT BAT

Fr. Triénope d'Afrique; Ger. Afrikanische Dreizahnblattnase

Triadenops afer Peters, 1877. Mb. Kön. Preuß. Akad. Wissen. Berlin 1876: 913. Mombassa, Kenya.

Taxonomy Although described as a species, *afer* was subsequently considered to be a subspecies of *Triadenops persicus* Dobson, 1871 (e.g. Simmons 2005), but it was restored to specific status by Benda & Vallo (2009). These authors place all African forms of *Triadenops* in this species, and consider *T. persicus* to be extralimital to Africa. Furthermore, these authors restrict *afer* to Africa and place specimens from Yemen, that were referred to as *T. p. afer* by Hill (1982b) and Koopman (1994), in *T. persicus*. Synonym: *majusculus* (Simmons 2005, Benda & Vallo 2009). Subspecies: none recognized by Benda & Vallo (2009): see Geographic Variation. Chromosome number (Kenya): $2n = 36$; $aFN = 60$. X = medium-sized metacentric; Y = small subtelocentric (Dulić & Mutere 1977).

Description Small microbat with noseleaf (posterior component with three tall projections); greyish-brown to medium brown with orange-phase; tail fully enclosed by interfemoral membrane; FA: 49–60 mm. Sexes similar. Pelage soft, fine, dense, silky with conspicuous sheen; mid-dorsal hairs 6–7 mm. Dorsal pelage greyish-brown; hairs greyish-brown with browner tip. Ventral pelage pale greyish-brown to beige. Orange-phase: dorsal and ventral pelage a spectacular brilliant rusty-brown with golden sheen. Ears small, widely separated, funnel-shaped, acutely pointed; height and breadth ca. equal; inner margin with central step-like emargination. Eyes minute. Muzzle broad and flat. Noseleaf as in Figure 65d. Posterior component divided into 13 cells (of which five on each side are conspicuous although sometimes obscured by pelage) and with three very prominent, pointed projections resembling a trident – hence the vernacular name of this genus. Central component with one smaller pointed process. Anterior component broad with two lateral leaflets on each side, and a deep median emargination, the sides of which are flexed upwards and recurved to form a process resembling an hour-glass in outline. Wings dark brown, slightly translucent; second phalanx of fourth finger with unique transverse spicule of bone projecting 2.5–3 mm outwards from proximal end into membrane (Figure 75). Interfemoral membrane dark brown; pelage extending onto proximal quarter of both surfaces.

Skull (Figure 75) narrow, elongated; braincase scarcely higher than rostrum; zygomatic arches not outwardly flared, each expanded dorsally into a broad plate; zygomatic width slightly greater than mastoid width. Rostrum with prominent nasal swellings. Sagittal crest well developed; supraorbital ridges weakly developed. Premaxillae unusually thick, with distinct ridge along line of contact that terminates anteriorly in upward-directed point. Upper incisor bifid. Canine with strong posterior secondary cusp reaching half

height of main cusp. Anterior premolar small, within toothrow but slightly displaced labially; canine and posterior premolar not in contact. M^3 not reduced and has three ridges (cf. *Asellia*).

Geographic Variation Prior to the recognition of *afer* as a valid species, two forms were recognized as African subspecies of *T. persicus* by Hill (1982b), Koopman (1994) and Simmons (2005):

T. p. afer: eastern Africa to Mozambique and E Zimbabwe (and extraliminally Yemen). FA: 49–56 mm; condylobasal length: 16.6–18.3 mm (Aellen & Brosset 1968, Hill 1982b).

T. p. majusculus: Uganda, Congo and Angola. FA: 53–60 mm, condylobasal length: 16.9–18.7 mm (Aellen & Brosset 1968, Hill 1982b).

Hill (1982b) reported that a series from West Nile District, Uganda is intermediate in size, although closer to *T. p. majusculus*. This suggested that the variation in Africa is possibly clinal. Subsequently, Benda & Vallo (2009) found no evidence for subspecific variation in *T. afer* and therefore consider *majusculus* to be a synonym of *T. afer*.

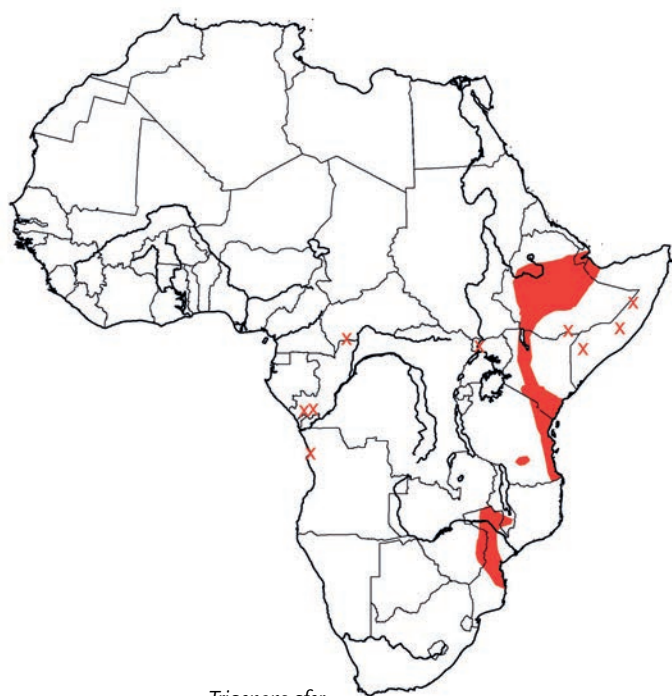

Similar Species Three other hipposiderids in Africa have three vertical projections arising from the posterior component of the noseleaf:

Asellia tridens. Tail protruding up to 7 mm beyond interfemoral membrane. Projections arising from posterior component of noseleaf short, triangular. Only one upper premolar on each side; M^3 greatly reduced (only two ridges).

Asellia patrizii. Smaller (FA: 38–43 mm; CrnC: 14.4–15.8 mm). Tail protruding up to 5 mm beyond interfemoral membrane. Projections from posterior component of noseleaf short, triangular. Only one upper premolar on each side; M^3 greatly reduced (only two ridges).

Cloeotis percivali. Smaller (FA: 31–39 mm; CrnC: 12.0–13.5 mm). Anterior component of noseleaf very narrow with deep median emargination; no process arising from sides of emargination. M^3 not reduced (four ridges).

Distribution *Triadenops afer* is endemic to Africa and is widespread in the Somalia–Masai Bushland, Afromontane–Afroalpine and Coastal Forest Mosaic BZs of Ethiopia, Djibouti and Somalia southwards to Zimbabwe and Mozambique, with separate populations in the Rainforest–Savanna Mosaics in Central African Republic (La

*Triaenops afer*

Maboké, MNHN 1198, 1199), Uganda, Congo and Angola (Funaioli 1971, Kock & Felten 1980, Aggundey & Schlitter 1984, Feiler 1986, Happold & Happold 1997, Pearch *et al.* 2001, BMNH, and other literature, all as *Triaenops persicus* or *T. p. afer*). Also Zanzibar I. (Hill 1982b).

Habitat Recorded in hundreds to thousands from coastal habitats in Kenya, Tanzania and Mozambique, and from numerous, widespread inland localities where, in contrast, only 1–12 individuals have been observed at a time. This suggests that *T. afer* is predominantly a coastal species, but this needs confirmation. Habitats include coastal forests of Tanzania (Cockle *et al.* 1998, as *T. p. afer*), dense trees and bush with maize cultivation near bank of Nile R. at Awash N. P., Ethiopia (Hill & Morris 1971, as *T. p. afer*), and farmlands with patches of miombo woodland, riverine forest and/or remnant rainforest, at 1000 m in Malawi (Happold & Happold 1997, as *T. persicus*). The presence of caves, mines or similar day-roosts is apparently essential.

Abundance Very common in some coastal localities where caves and mines are present (see Habitat).

Adaptations Has narrower wings than typical for hipposiderids; aspect ratio medium; wing-loading low. Flies slowly with fluttering, butterfly-like wing-beats and great manoeuvrability. Can take off from ground. Turns by banking (radius of turn <25 cm) and by stalling-and-twisting; sustained flight in a 1 × 1 × 1 m enclosure for up to four circuits/flight (3 bats, 10 flights each; M. Happold unpubl.). By day, hangs freely in caves and mines; one cave in Mozambique was humid and very warm (Dalquest 1965, as *T. p. afer*). Often shares caves with *Coleura afra*.

Foraging and Food Emerges from day-roost in evening, sometimes before dark. Forages low over ground and bushes (Harrison 1964, Hill & Morris 1971). Faecal material from 'a few'

individuals contained abundant scales of Lepidoptera (Matthews 1941).

Echolocation Call-shape CF/FM. CF-frequency appears to be very variable. Pye (1972) found CF-frequencies distributed bimodally with the following combinations: 77.0–80.5 kHz and 85.5–89 kHz (7 bats recorded in isolation), 75–77.5 kHz and approximately 85.5–88.5 kHz (bats foraging in wild). CF-frequencies of 72–75 kHz (2 ♂♂, hand-held) and 80–85 kHz (1 ♀, hand-held) were recorded in Malawi (Figure 64) (M. Happold unpubl.). The possibility that ♂♂ and ♀♀ emit different frequencies might explain the bimodal distribution of CF-frequencies, but this needs confirmation.

Social and Reproductive Behaviour In coastal habitats, roosts in very large groups (hundreds to thousands; possibly more) (Kulzer 1959, as *T. persicus*, Dalquest 1965, as *T. p. afer*). Hangs, apart, in clusters (Smithers 1983, as *T. persicus*).

Reproduction and Population Structure No conclusive data. In Tanzania, spermatogenesis was high in Jun–Oct, low in Dec–Jan (Mainoya 1979). At 05° 03' S (Amboni Cave, coastal Tanzania), 2 of 6 ♀♀ were pregnant in Dec; each had one foetus (Matthews 1941). Also in Tanzania, births were reported in Jan (Anciaux de Faveaux 1972).

Predators, Parasites and Diseases Ectoparasites include a flea *Araeopsylla scitula* (Siphonaptera: Ischnopsyllidae) (Beaucournu & Kock 1996, as *T. p. afer*); seven species of bat-flies (Diptera: Nycteribiidae, Streblidae); nine species of mites (Acari: Spinturnicidae, Macronyssidae, Myobiidae, Chirodiscidae, Sarcoptidae) (Radovsky & Yunker 1963, Anciaux de Faveaux 1984, as *T. persicus*).

Conservation IUCN Category for *Triaenops persicus* (*sensu* Simmons 2005): Least Concern.

Family MEGADERMATIDAE

FALSE VAMPIRE BATS

Megadermatidae H. Allen, 1864. Monogr. Bats N. Am., pp. xxiii, 1.

| | | |
|--------------------------------|-------------------|--------|
| <i>Cardioderma</i> (1 species) | Heart-nosed Bat | p. 403 |
| <i>Lavia</i> (1 species) | Yellow-winged Bat | p. 406 |

The family Megadermatidae is polytypic and confined to the tropics of the Old World and Australasia. There are four extant genera and five species with two monotypic genera in Africa. They have enormous ears, which are partly joined together (Figure 32d). They also have a prominent noseleaf, a large interfemoral membrane and the tail is vestigial or absent (Figures 33d and 76a).

African megadermatids are small to medium-sized microbats with long grey or greyish pelage. The head is rounded, the muzzle short with a conspicuously long, erect noseleaf. The ears are longer than the length of head and are partly joined together for at least a third of their length by a membrane between their inner margins and the forehead. The tragus is long and uniquely bifid. The eyes are large for a microbat. The wings are large and broad; the second finger has a long metacarpal and one phalanx. The hindlimbs are long and the toes (except hallux) have three phalanges. The tail is vestigial or absent. The interfemoral membrane is large and broad, and is partly supported by calcars. Females have one pair of pectoral nipples and one pair of pubic nipples. The skull (Figure 76) is characterized by the loss or extreme reduction of the premaxillae and the concomitant loss of the incisors. Even if present, the minute remnants of the premaxillae are lost during preparation of skulls and therefore the greatest length of the skull (GLS) is taken to be the distance from the front of the maxilla to the most posterior part of skull. As in the family Nycteridae, there is a broad frontal plate formed by the fusion of flattened postorbital processes with the supraorbital ridges; this plate unites with a shallow sagittal crest. There is no lambdoid crest. The palate has a very deep-wide emargination between the canines, which sometimes reaches beyond the first premolars. The dental formula is $0^{113}/_{2123} = 26$ (except in one non-African species, which has two upper premolars).

Megadermatids have large wings, low to very low aspect ratios and medium to high wing-loadings. Their flight is slow and manoeuvrable; they can take off from the ground and can exploit cluttered environments. They are not adapted for cursorial locomotion or for climbing. Most megadermatids feed on insects and small vertebrates; an exception is the African *Lavia frons*, which seems to feed only on insects. The common name of the family, false vampire bats, stems from the old, erroneous belief that they fed on blood, as do the true vampire bats of the New World. There are no blood-sucking bats in Africa. Like nycterids, megadermatids sometimes forage and catch small prey by slow-hawking, but more often they are perch-hunting fly-catchers and gleaners, and carry larger prey back to the perch before eating it. Prey is detected visually and/or from sounds made by the prey, and also by echolocation. Like nycterids, megadermatids are 'whispering bats' whose echolocation calls are low intensity, multiharmonic CF calls of short duration, which provide detailed information about close objects, and are particularly well suited to densely cluttered environments (Möhres & Kulzer 1957, Möhres & Neuweiler 1966). The echolocation calls are probably emitted

through the nostrils and modified by the noseleaf. During the day, megadermatids roost in caves, crevices, hollow trees and buildings, or in the foliage of bushes or trees (Nowak 1999). Some roost singly, some in pairs, others in groups ranging in size from small to very large. *Lavia frons* establishes long-lasting monogamous pair-bonds and is territorial (Vaughan & Vaughan 1986). *Cardioderma cor* roosts in colonies and its mating system is not known, but individuals establish foraging territories, which are advertised by 'singing' (Vaughan 1976). Other megadermatids roost in groups of mixed composition throughout most or all of the year: ♀♀ of two species establish maternity colonies. The litter-size is typically one but is occasionally two in the case of one Asian species. Reproductive chronologies include restricted seasonal monoestry (in the Australian *Megaderma gigas*), seasonal bimodal polyoestry (in the African *C. cor*) and perhaps others.

The geological range of the family Megadermatidae is early Oligocene to Recent in Africa, early Oligocene to early Pliocene in Europe, middle Miocene to Recent in Australia and Pleistocene to Recent in Asia (Koopman 1984, Hand 1985, Koopman & Jones 1970). Apparently, there were many more species of megadermatids in the past, which may explain the diversity of the adaptations exemplified by the four extant genera. These genera are *Macroderma* (one species in Australia), *Cardioderma* (one species in Africa), *Megaderma* (two species in Asia) and *Lavia* (one species in Africa) (Koopman 1994). Based on hyoid morphology, *Macroderma* is considered phylogenetically primitive and somewhat removed from the other genera (Griffiths *et al.* 1992). *Macroderma gigas* (FA: 96–113 mm) and the African hipposiderid *Hipposideros gigas* (FA: 95–124) are the largest living microbats.

Megadermatids are almost entirely tropical but exploit habitats ranging from rainforest to semi-deserts. Both of the African species are tropical and both are mainly woodland savanna species that are also found in some forests (but not lowland rainforests). They are almost always found below 1000 m. At some localities, they have been recorded sympatrically.

Based on morphological data, the family Megadermatidae was placed in the superfamily Rhinolophoidea with the families Nycteridae, Rhinolophidae and Hipposideridae (Simmons 1998, Simmons & Geisler 1998), but more recent molecular studies have contradicted many groupings based on morphological data and therefore Simmons (2005) does not recognize any of the chiropteran superfamilies.

The genera in Africa are:

Cardioderma. Noseleaf 9–14 mm; pelage grey without yellow tinge; frontal shield of skull strongly concave, minimum breadth of shield 5.3–6.2 mm (see also Figure 76).

Lavia. Noseleaf 19–26 mm; pelage bluish-grey usually with yellowish tinge; frontal shield of skull comparatively flat, minimum breadth of shield 6.8–7.9 mm (see also Figure 76).

GENUS *Cardioderma***Heart-nosed Bat**

Cardioderma Peters, 1873. Monatsber. K. Preuss. Akad. Wiss. Berlin 1873: 488. Type species: *Megaderma cor* Peters, 1872.

Cardioderma is a monotypic genus confined to the northern half of eastern Africa. Distinguished from the other African genus in the family Megadermatidae by the comparatively shorter length of the noseleaf (9–14 mm), the absence of any yellowish tinge in the pelage, and the strong concavity of the frontal shield together with its

comparative narrowness (minimum breadth 5.3–6.2 mm) (see also Figure 76). The only species is *C. cor*.

Meredith Happold

Cardioderma cor.

***Cardioderma cor* HEART-NOSED BAT (AFRICAN FALSE VAMPIRE BAT)**Fr. *Cardioderme à nez en coeur*; Ger. *Herznasen-Fledermaus**Cardioderma cor* (Peters, 1872). Monatsber. K. Preuss. Akad. Wiss. Berlin 1872: 194. Ethiopia.

Taxonomy Originally *Megaderma cor*. Synonyms: none. Chromosome number: not known.

Description Small microbat with noseleaf and very large interfemoral membrane but no tail; pale grey with brown wings and white digits; ears enormous and partly joined; tragus bifid; noseleaf erect and comparatively short (9–14 mm). Sexes similar. Pelage loose; mid-dorsal hairs 14–15 mm. Dorsal pelage pale grey, sometimes bluish, never suffused with yellow; hairs unicoloured. Ventral pelage slightly paler, never yellowish. Noseleaf as in Figure 76b; erect, somewhat heart-shaped, 9–14 mm (cf. 19–26 mm in *Lavia frons*). Ears pale brown, almost twice as long as head, basal halves joined by interaural membrane. Tragus bifid; outer lobe tapering to fine point; inner lobe less than half length of outer lobe, squarish or rounded (Figure 76d). Eyes very large for a microbat. Wings very broad, sepia brown, semi-translucent; skin over forearms and finger-bones white or whitish. Interfemoral membrane sepia brown. No tail.

Skull as in Figure 76f, h and j. Frontal shield strongly concave and relatively narrow (cf. *L. frons*); minimum breadth 5.8 (5.3–6.2) mm, $n = 15$. For additional data, see Csada (1996) but note that the photographed skull is that of *Coleura afra*, see p. 496.

Geographic Variation None.

Similar Species There is only one other megadermatid in Africa:

Lavia frons. Noseleaf longer (19–26 mm). Pelage bluish-grey with yellow tinge; skin over wing-bones not white. Frontal shield of skull comparatively flat; narrowest part broader (6.8–7.9 mm).

Distribution Endemic to Africa. Recorded mainly in the Sahel Savanna, Somalia–Masai Bushland and Coastal Forest Mosaic BZs, but extends marginally into the Afromontane–Afroalpine BZ of the Ethiopian Highlands along the Ethiopian Rift Valley. Recorded from Sudan, Eritrea, Djibouti, Ethiopia and Somalia to Uganda, Kenya and C Tanzania (including Zanzibar I.) (Swynnerton & Hayman 1951, Kulzer 1959, 1962, Funaioli 1971, Largen *et al.* 1974, Koopman 1975, Aggundey & Schlitter 1984, Varty & Hill 1988, Yalden *et al.* 1996, Cockle *et al.* 1998 and others). Possibly not distributed throughout Somalia as was indicated by Kingdon (1974) without supporting evidence, and Csada (1996). Reported to occur in N Zambia by Kingdon (1974) but not by Ansell (1978), and there are apparently no confirmed records from this region.

Habitat Recorded from both dry and moister habitats in *Acacia–Commiphora* deciduous bushland and thicket, semi-desert grassland and shrubland, and coastal forest mosaic vegetation zones. Also recorded from one of the coastal forests in Tanzania (Cockle *et al.* 1998), from riverine forest in Somalia in dry season (Varty & Hill 1988) and from open grassland and thorn scrub with volcanic rubble and lava blister caves, at ca. 1000 m, in Awash N. P., Ethiopia (Hill & Morris 1971).

*Cardioderma cor*

Abundance Uncertain. Moderately common in museum collections.

Adaptations Aspect ratio very low; wing-loading not known; wing-tip rather long. Flight slow and manoeuvrable. Can take off from ground; can hover briefly (Vaughan 1976, O'Shea & Vaughan 1980). By day, hangs free in caves, hollow baobabs *Adansonia* and abandoned Masai huts (Vaughan 1976). Seldom shares roosts with other species, but Kulzer (1962) found *C. cor* sharing one cave with *Rousettus aegyptiacus*, *Coleura afra*, *Taphozous hildegardeae*, *Rhinolophus* sp. and *Hipposideros* sp. While roosting, individuals are constantly vigilant and easily disturbed, suggesting *C. cor* does not become torpid.

Foraging and Food *Cardioderma cor* is a specialized perch-hunter, which forages by fly-catching and by ground-gleaning and leaf-gleaning, in feeding territories that are advertised by 'singing' (Vaughan 1976, McWilliam 1987a, Ryan & Tuttle 1987). No other African bat is known to do this. Ground-gleaning (mainly for large beetles but also for centipedes, scorpions and cockroaches) predominates during the dry seasons when grass-cover is reduced by termites. Perches are usually twigs of *Acacia* or *Commiphora*, 0.3–3.5 m above ground. Interlacing thorny or spiny branches above the perches provide protection from predators. Perching bats are also camouflaged by their wings, which resemble bunches of leaves, the white digits mimicking the veins of the leaves. For much of the year, individuals of both sexes occupy feeding territories, 0.1–1.01 ha ($n = 4$), each containing a series of habitually used perches (see Social

and Reproductive Behaviour). Perches are located over ground that is covered during the dry season by dead leaves and detritus, which produce characteristic sonic and ultrasonic sounds when disturbed by potential prey. These sounds (not vision or echolocation) indicate the position of potential prey. While listening for prey, individuals rotate through almost 360 degrees and, when perched 2 m above ground, scan an area ca. 4 m in diameter. They glide down, often snatch the prey without landing, sometimes land and immobilize the prey, sometimes hover after an initial unsuccessful attack, and finally carry the prey to the perch for eating. Flights to capture prey and to move between perches are usually of less than five seconds duration (details in Vaughan 1976). In wet seasons, when tall grass prevents ground-gleaning, and flying insects and leaf-eating insects are abundant, the bats switch to fly-catching (mainly for large flying beetles and hawk-moths; occasionally for small bats) and leaf-gleaning (mainly for Orthoptera). Although captive individuals eat frogs, there is no evidence that frogs are eaten in the wild (Ryan & Tuttle 1987). Changes in population density suggest that *C. cor* sometimes disperses seasonally from dry areas (where insects are scarce) to moist refugia such as riverine and coastal forests (Vaughan 1976, O'Shea & Vaughan 1980, Varty & Hill 1988). However, dry season ground-gleaning for large prey, with minimal expenditure of energy while searching for prey, and the exclusive utilization of previously established foraging territories, are highly adaptive to dry season conditions in dry habitats, and enable many individuals to exploit these habitats year-round.

Echolocation Although terrestrial prey is located by prey-generated sounds, *C. cor* uses both vision and echolocation to perceive its surroundings. The echolocation calls are FM sweeps (Pye 1980) with peak-frequency 42 kHz (O'Shea & Vaughan 1980) or 56.7 ± 11 kHz (Taylor *et al.* 2005). The calls are of low intensity, broad bandwidth (40–90 kHz) and short (2 ms) (Taylor *et al.* 2005). Four harmonics are present in at least some calls (Pye 1980).

Social and Reproductive Behaviour Roosts in groups (colonies); up to 80 found in hollow baobabs (Vaughan 1976). Wide spacing is maintained between individuals. Colony-composition and mating system not known. Despite roosting in colonies, individuals often forage singly. They establish foraging-territories, which, at least in the case of ♂♂, are advertised and delineated by singing, as in many passerine birds. In inland Kenya, each territory is held by a single individual or a mother–young couple. Territorial song consists of 4–9 (usually six) high-intensity pulses with fundamental frequency ca. 12 kHz (audible to humans), each song lasting ca. 1 sec. Singing occurs while ♂♂ are hanging from their foraging-perches. Inland, there is no singing during the short wet season, regular singing several times/min during the long wet season and early long dry season, and low-rate singing during the remaining dry periods. Thus territories are established when food is maximally abundant, but have their greatest survival value at the end of the long dry season when insects are most scarce (Vaughan 1976). In contrast, in coastal Kenya, there is pronounced territorial singing in the long dry season, and territories are sometimes occupied by male–female pairs that interact by sharing perches and flying together (McWilliam

1987a). Only ♂♂ were heard singing. Females make soft twittering vocalizations, possibly associated with mating. The differences in behaviour of inland and coastal individuals possibly reflect differences in reproductive chronology, lower inland population densities, and the dispersal of some inland individuals away from dry habitats during the long dry season. In addition to territorial singing, *C. cor* also makes a 'flight call' (a series of pulses more widely spaced than songs), which perhaps is a long-range location-call serving to inform individuals of each other's locations and directions of flight (Vaughan 1976).

Reproduction and Population Structure Litter-size: one. At ca. 2° S (near Kibwezi, inland Kenya), reproductive chronology is seasonal bimodal polyoestry with births during the wettest month in the short wet season (Nov) and at beginning of the long wet season (Mar–Apr) (Vaughan 1976). At ca. 4° S (Diani Beach, coastal Kenya [where rainfall is bimodal, insects most abundant in the wet seasons, less abundant in the short dry season and scarce in the long dry season]), very limited data suggest a different chronology (possibly aseasonal polyoestry with births peaking in the wet seasons but also occurring in the long dry season) (McWilliam 1987a). More data are needed from coastal habitats.

Predators, Parasites and Diseases Ectoparasites include bat-flies *Basilia daganiae* (Diptera: Nycteribiidae), *Raymondia huberi*, *R. planiceps*, *R. seminuda* (Diptera: Streblidae); a tick *Carios boueti* (Acari: Argasidae); and a mite *Megadermicolus yunkeri* (Acari: Chirodiscidae) (Anciaux de Faveaux 1984).

Conservation IUCN Category: Least Concern.

GENUS *Lavia*

Yellow-winged Bat

Lavia Gray, 1838. Mag. Zool. Bot. 2: 490. Type species: *Megaderma frons* E. Geoffroy, 1810.

Lavia is a monotypic genus confined to Africa. Distinguished from the other African genus in the family Megadermatidae by the comparatively long length of the noseleaf (19–26 mm cf. 9–14 mm in *Cardioderma*) and a yellowish tinge in the pelage, the flatness of the frontal shield of the skull, which is also broader at its narrowest part

(minimum breadth 6.8–7.9 mm).
